# THE NATION'S HEALTH

(Continuing MODERN MEDICINE)

*A Monthly Magazine Devoted to Community Health with Special  
Reference to Industrial and Institutional Health Problems*

Volume IV

Chicago, January 15, 1922

Number 1

## A Significant Public Health Message

BY H. S. CUMMING, SURGEON GENERAL, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

IF WE review the public health work of the country during the past year, the prospects of the new year should encourage all of us who work in the field of preventive medicine and public health. Marked as the year was by a period of profound economic depression, social unrest, and financial stringency, I think one thing upon which the public health workers are to be congratulated is that in the face of drastic retrenchment in all other respects, public health funds have suffered the least of all appropriations and outlays. This can mean but one thing—the dependence of national prosperity upon national health has ceased to be submerged in the public consciousness, and the necessity for adequate health protection is now a generally accepted fact—a fact backed by public opinion and which the taxpayers are willing to finance.

### Proofs of Gains

Let us refer briefly to some of the figures relating to the prevalence of preventable disease and contrast conditions as they now exist with the conditions, say, of a decade ago. Thus we find that the death rate from tuberculosis for the United States in 1910 was 160.3 and for 1920, 114.2. Again, in 1910 the general typhoid fever death rate was 23.5 per hundred thousand population, in 1920, 7.8. It is safe to say that if in 1910 the statement had been made that in ten years' time the typhoid fever death rate would be only one-third of the figures at that time, the sanitarians generally would have been pro-

foundly sceptical of any such prediction.

There are no considerable figures available from which an accurate statement can be made regarding the infant mortality rate for the United States in 1910, but a conservative estimate would make the rate approximately 124 per thousand births. In 1920 the infant mortality rate in the birth registration area of the United States was 86 per thousand births, a clear gain of approximately 38 points in the last ten years. As a means to further reduce this rate may be noted the passage of the Sheppard-Towner Maternity bill by virtue of which Federal funds are made available to the states. These funds will undoubtedly initiate much work on the part of the States and local communities to preserve maternal and infant life.

Again, in 1910 the scarlet fever death rate was 11.6 per hundred thousand population and in 1920 it had fallen to 4.6. This illustrates the efficacy of general measures for the control of communicable diseases which play such an important part in the organization and activities of our various state and local departments of health.

The mortality from diphtheria shows the advance of preventive medicine in the control of this dread disease of childhood. The death rate from diphtheria in 1910 was 21.4 per hundred thousand population and in 1920 it had sunk to 15.3.

In 1910 the death rate from diarrhea and enteritis in children under two years of age was 100.8; in 1920 this had dropped to 44.0. Thus has

the toll taken by this scourge of infant life been reduced by more than half.

So much then for the bright side of the shield.

### Where to Focus Attention

Let us now take account of some of the disease problems which face us and for which we must still perfect our measures of prevention. We should not become too complacent over the mastery already accomplished over the diseases just mentioned, in view of the terrific lesson taught us by the influenza epidemic of 1918-1919, and also the figures about to be given in relation to the prevalence of diseases of middle life, such as pneumonia, cancer, heart, and kidney diseases.

In 1910 the general death rate from pneumonia, all forms, was 147.7 per hundred thousand population, and in 1920 this death rate was 137.3. We have, therefore, made but relatively little advance in the problem of pneumonia control. The death rate from acute nephritis and Bright's disease was 99 in 1910 and had declined but to 89.4 in 1920. The death rate from cerebral hemorrhage, or apoplexy, in 1910 was 73.7 per hundred thousand population and rose to 80.9 in 1920. The case is similar as regards cancer. The death rate from this disease in 1910 was 76.2, in 1920, 83.4, an increase of over 7 points per hundred thousand population. Again, the death rate from organic diseases of the heart was 141.5 in 1910 and the figures of 1920 show the rate to be 141.9, showing that no reduction

from this great cause of death has taken place.

A preliminary stocktaking of the kind we have just outlined serves to show us where our health problems lie. That our measures against some of the communicable diseases have been fraught with so much success encourages us to undertake the difficult problems of the control of such diseases as organic heart diseases, cancer, pneumonia, kidney diseases, and the like.

Apart from the control of these diseases one of the crying needs of the country is better organization of health work in the rural communities. A survey made by the Public Health Service two years ago showed that only 3 per cent of our rural districts had adequate local health organizations. It is a pleasure to an-

nounce that this number has increased during the past two years from 3 to 6 per cent. This only emphasizes the inadequacy of health service in our rural communities.

It is safe to state that if all of the rural communities were provided with adequate health organizations a tremendous step in advance would have been taken toward the solution of the national health problems. It is full of encouragement, however, to note that the value of preventive health work has been so impressed upon our rural district governments as practically to double during the past two years the number of local health organizations, and we may hope that the increase in the number of health organizations in rural communities will continue in the same proportion.

The future is full of wonderful possibilities for the control of diseases which have up to the present time eluded mastery. Federal, state, and local health authorities, universities and other foundations for health have their corps of trained medical and sanitary personnel working in laboratories, hospitals, quarantine stations, and health departments. These trained observers will doubtless give as good an account in achievement of their work as those who have made the history of preventive medicine to date. The establishment during the year of schools of hygiene in connection with our large universities will insure for the future an increase in the supply of enthusiastic, well trained men and women who have taken up the great profession of public health as their life work.

## The Venezuelan Sanitary Renaissance

BY OUR LATIN-AMERICAN CORRESPONDENT

TO THE approaching traveler by sea, La Guayra is a brick-red, sun-baked incrustation on the face of Nature, sprawling precariously at the base of a range of mountains which rise abruptly from the sapphire Caribbean. To the sanitarian with a long memory, it is an anathema, for time once was when it was a plague focus of the worst sort, a menace to every nation whose vessels dropped anchor in that little harbor which is Venezuela's principal port. A departing consul summed up his opinion of the city in a doggerel which has been carbon copied and passed from hand to hand for many years until it has been scattered to

the seven seas much in the same manner as "La Ville de St. Nazaire" ran like wildfire through the A. E. F.

Adios,<sup>1</sup> sucia<sup>2</sup> La Guayra,  
City of the agile flea,  
Mañana, gracias a Dios,<sup>3</sup>  
I say adios<sup>4</sup> to thee!

From your filthy sunbaked cerro,<sup>5</sup>  
Where los chivos negros<sup>6</sup> roam,  
I board a rolling buque,<sup>7</sup>  
And I head for home sweet home.

Farewell, ye gloomy casas,<sup>8</sup>  
Naked children, moscas,<sup>9</sup> heat  
Where the hungry cucarachas<sup>10</sup>  
Eat the socks from off your feet.

Where ropas<sup>11</sup> lavenderas<sup>12</sup> wash,  
Whene'er they're so inclined,

And hotel waiters strut about  
With shirt tails out behind.

Where streets are all retretes<sup>13</sup>  
For niños,<sup>14</sup> perros,<sup>15</sup> men,  
Where ratas<sup>16</sup> die at noonday  
And their fleas hop off again.

Where el agua<sup>17</sup> teems with live-stock,  
Where at dawn the burros bray,  
And the bells in las iglesias,<sup>18</sup>  
Clatter through the livelong day.

Farewell, ye grimy cuidad,<sup>14</sup>  
Con sus, chinches, pulgos,<sup>20</sup> stench,  
I leave you, amiguitos,<sup>21</sup>  
Yes, without a single wrench.

But a new spirit is abroad in La Guayra and now it sits blinking in the glaring sunlight, a plague-free, relatively rat-proof town. It has an efficient health officer, Dr. Las Casas, who, under the direction of Dr. L. G. Chacin Itriago, the Director de Sanidad Nacional, has already accomplished wonders.

There is now a central Health Office with a small but well equipped laboratory where the rodent catch is necropsied, mosquitoes identified, stool examinations made, and various sorts of diagnostic work carried on. A safe water supply has been put in, a modern sewerage system is being installed, the wharves, docks, and warehouses have been rat-proofed

Rat-proof, small-boat landing and warehouse, La Guayra, Venezuela

*Glossary:* 1, Goodbye; 2, dirty; 3, tomorrow, thank God; 4, goodbye; 5, hill; 6, the black goats; 7, ship; 8, houses; 9, fishes; 10, cockroaches; 11, linen; 12, washerwoman; 13, privies; 14, children; 15, dogs; 16, rats; 17, the water; 18, the churches; 19, city; 20, with your bedbugs, lice; 21, little friends.

A general view of La Guayra, Venezuela

and a fine concrete quarantine and immigration station is in process of erection. The thoroughness with which these things have been done is evidenced by the fact that recently after an inspection by one of its sanitary officials, the Panama Canal lifted the quarantine restrictions which it had imposed for many years against passengers from La Guayra and other Venezuelan ports.

The sanitary improvement of La Guayra means much to other ports of the Caribbean littoral as well as to those of Europe, since it is an important port of call and trans-shipment point. It is connected with Car-

A view of the new quarantine station, La Guayra, Venezuela

acas, the capital of the Republic, by railway and a splendid automobile road. Macuto, a charming seaside resort, is only a few moments away by railway or auto. The nearest port is Puerto Cabello, so called because its harbor is so excellent that the Spanish explorers thought a ship could be moored there by a hair (cabello). A movement is now under way for the erection of a modern quarantine station there and the attacking of the malaria problem, which is very serious.

The work which has been accomplished at La Guayra should be a stimulus to other South American ports.

## The Compelling Health Cartoon

MAN is still in the picture-writing stage of development, despite the wellnigh universal use of the printed or written page, and he who would teach, particularly he who would attempt group instruction, must depend upon this means of communication. Health workers have in part realized this and some very creditable cartoons have been brought out, particularly by the United States Public Health Service and the Illinois Department of Health. The fact remains, however, that the use of really good health cartoons is not sufficiently wide spread and, taken by and large, the average health cartoon is poorly conceived and wretchedly executed. As compared with other classes of this form of art, health cartoons are at the bottom of the list, largely because the monetary rewards for this kind of service are insufficient to attract men of genuine

ability and adequate educational background. We need somebody to do for health what Coles Philips did for stockings, E. W. Kimball for the American negro, and A. B. Frost for fishing. The health officer who will secure a Leyendecker or a McCutcheon and keep him hard at work will reach a larger audience, and more effectively than by any other means.

Who has not chuckled over the chubby twins who extol a certain brand of soap? Who cannot recall the joy of Palmer Cox's brownies and their adventures with a soap which floats? Who has not taken careful heed of the words of battery wisdom emitted by the man in overalls and who does not love Aunt Jemina and Uncle Joe? If the prosaic articles of commerce which these mythical characters proclaim can be thus popularized, how much more widespread would be the application of this graphic art to the wonderful story of health, its enemies and its protectors?

This is a specimen of Poulbot's art, so freely employed to help his country.

\*The illustrations used in connection with this article are supplied by courtesy of Dr. Theodore C. Merrill, Director, Department du Nord, American Red Cross, France.

The recent child welfare conferences in France made effectual use of poster display. Among the pictures was the work of Miss Upjohn of the United States, Madame Dick Dumas of France, and Poulbot, the noted child-life artist of France.

A good health cartoon must, first of all, be arresting; it must run out and grab the beholders fancy with a vise-like grip, it must catch his eye and hold it until the idea has penetrated clear up to the hilt and "registered."

To do this, it must be just bizarre

A posed poster. Boy Scouts are often called "Boy Scouts" in France

enough to attract attention, yet not too unusual, because the idea of faddism must not be given. The arresting feature must be pertinent to the thought to be transmitted, e.g., a picture of a sailor in a high silk hat would attract the eye but would tell no story, whereas a sailor running away from a street walker would, when properly captioned, engage attention and hold it until the idea of avoiding venereal disease had sunk home.

The execution of the drawing must be good. An amateurish cartoon gets nowhere. It must be clear; it must be simple; it must convey one lesson and only one; and it must have a "wallop." "Above all, it must be logical. Whenever possible, it must contain a little glint of humor, but it must not be too broadly funny lest the mind of the beholder be distracted from the big idea, and it must never shoot over the head of the audience. On the other hand it must never hit them in the feet. In other words the cartoon must be accurately aimed. This means that there must be a kernel of broad human understanding in the picture. Unless a special group, e.g., the bluejackets at a training station, is to be reached, the figures in the picture should be just average, natural-looking people, then the story fits practically everybody. The picture must contain action. A public whose chief literary pabulum is the filmed exploits of Hairbreadth

Harry, cannot be attracted by the old fashioned still-life figures with loops of conversation spouting from their faces as was the mode in those distant days when spades counted two.

The grewsome, should, on the whole, be avoided as should also the disgusting, the prurient and the frankly pathological, bearing in mind that the end sought is to attract not to repel. Threats should be avoided also. The souls of humanity were menaced with pit-fire for many generations without appreciable effect on general morality before it was discovered that gentle teaching made many permanent converts. The aim of the health cartoon is to turn the feet of the sinner against sanitary morals into the paths of hygienic righteousness, not to make a forcible or eleventh hour conversion. It should be borne in mind that the perfect health cartoon is a pill which the public is to be induced to swallow, therefore, it must be well sugared and gilded but the gilding must be soluble and the sugar coating must not be cloyingly sweet.

### Universal Symbolism

Since a cartoon is essentially the method of transferring thought by symbols, the use of symbols must be free and logical. This is exemplified in the political cartoon, where a set

Miss Upjohn created this poster to help children everywhere

These figures are typical of Poulbot's types

of teeth, a donkey, a camel, an elephant, a hatchet and cherry tree are used to convey definite ideas, similarly, in the health cartoon a Prince Albert coat means that the undertaker is on the job, a white cap and apron or an ambulance, a very

The original of this poster by Miss Upjohn is in the American Red Cross Museum at Washington.

ill person, and a wolf, hunger. A symbol standing for health, just as Uncle Sam stands for the United States and John Bull for England, is much needed, if for no other reason, because it will abolish the vandyke beard and obstetrical bag supposed to represent the medical profession.

The writing of caption is an art all by itself. Many a good cartoon needs none whatever and has been marked because someone could not resist the temptation to make assurance doubly sure by adding an unneeded explanation. Captions should be complimentary to the cartoon; they should be short, pithy, and carry a punch.

They should never state the obvious nor the platitudinous. They should be very simple, and if they can be put into a mentally adhesive jingle so much the better.

Spasmodic advertisement is a waste, to be really effective it must be continuous. So it is with health cartoons, if they appear regularly, if they are good enough, if they are telling, if they hammer the health idea home and clinch it, by and by, results will be seen. There will be a heartier cooperation on the part of the public, it will have an interest in the health officer's work, and it will be quickened to healthier, saner living.

## The Blight of Fear

By BERENICE C. SKIDELSKY, NEW YORK CITY

**T**HERE is nothing so potent, according to Thomas Hardy, the eminent English novelist, as fear well maintained.

Fear's undeniable potency, unfortunately, is in the direction of evil. Fear paralyzes initiative, it destroys the will, it reduces the individual to a trembling automaton instead of permitting him to be a free-stepping, self-directing personality.

And yet, despite its distressing effects, fear is one of the most favored weapons in the hands of untutored parents to obtain obedience from their children and to make them "good." The fretful child, demanding something that is not good for him or that it is not expedient for him to have, is told that the bogey man, horribly tusked, is waiting just around the corner to eat naughty little boys who ask for such things. Thereupon, though his eyes widen with terror, his crying is hushed, and the mother has what she mistakenly terms "some peace." She does not realize the evil effects of the fear that has probably turned inward, nor does she suspect that she may be laying the groundwork for later nervous upset in her child—the source of far more disturbance to her peace than a moment's crying.

### Early Fears Persist

Modern students of child psychology are practically unanimous in declaring that threats and stories about ghosts, goblins, and other childhood bugaboos, who live in the dark and prey upon little children, create a vivid, lasting and harmful impression upon the minds of very young chil-

dren. Dr. A. R. MacKenzie, specialist in mental and nervous diseases at Huntington State Hospital, West Virginia, corroborates the idea in emphatic terms.

"The bogey story," he says, "is all wrong. Children who are made to mind through fear of some unseen horror, about which their thoughtless parents or nurses may tell them, and in which they believe with all their little hearts, may actually become insane in consequence of the impressions created on their young minds. The dementia may take any one of various forms. It is a pathological condition."

In illustration, Dr. MacKenzie tells of a case of insanity which grew out of impressions created in childhood by a thoughtless nurse in a child who, up to the age of five, had been perfectly normal—sweet and lovable, devoted to her mother, and happy for hours with her toys. A new nurse came who, in order to make her "behave," threatened her with a bogey man who was lying in wait for her. To drive home the threats, the nurse frequently left the child alone on a deserted road in the dark. At the end of two years the little girl was well nigh unmanageable. This was the forerunner of a mental breakdown a few years later.

Mrs. Margaret J. Powers, director of Social Service and a member of the Mental Hygiene Committee, under the auspices of the New York State Charities Aid Association, is another specialist whose experience has caused her vigorously to denounce the weapon of fear in the training of children. She tells of a

These children at the Silver Cross Day Nursery are enjoying the play that is recreation. Children must play all the time and grown-ups much of the time if the personality is to have its fullest expression.

boy of eleven, nervous and irritable, and with an uncontrollable temper, who in the process of psycho-analysis admitted to dreams in which movies with hair-raising plots figured largely.

She tells another pathetic story of a girl of twelve, with a stepmother a little inclined to favor her own children. The child's mother died when she was not quite two years old; and two years later, the little girl was sent to Italy to some relations of her father's. There she was badly beaten, and thoroughly frightened. She came back to America a few years later, with intelligence normal but spirit absolutely broken. Her father's tactics were not unlike those of his brother in Italy, and she continued to be subjected to the same terrorizing processes as in her earlier years. When kept after school she had attacks of acute hysteria, induced by anticipation of the parental displeasure at her late homecoming. Upon one occasion she forged a report card rather than take home one with an unsatisfactory record. Mrs. Powers, in taking charge of the case, got the family to change its attitude a little. But when the father, thanking her for her interest in the child, put it on these grounds: "I want some one to keep the fear in her,"—Mrs. Powers realized how hopeless is a certain kind of parental outlook.

One of the factors in human psychology most to be reckoned with in educational methods is the intense

love of a story which is inborn in every one. The recital of deeds performed and events that take place is a source of never failing fascination, especially to the young mind, unwearied by satiety, to which the most commonplace happenings become in the telling a great adventure.

It becomes apparent, therefore, that just as stories wrongly selected are of deplorable influence upon the growing mind, so stories whose choice

is backed by wisdom and understanding will do much to strengthen mentality and character.

"Fear," says Mrs. Powers, "has no biological place in the civilized community. The work of education is to build up courage patterns instead."

This fact is deeply understood by the leaders of Community Service, who have in many communities introduced story-telling as a phase of recreation, with trained story-tellers in charge. The success of these groups has been complete, and the children fortunate enough to be part of them are having their little minds soothed and brightened by interesting tales that do not curdle the blood nor raise the hair in horror. The stories are carefully selected not to terrify and thereby crush the little spirit, but to encourage and thereby liberate it. Intelligent outsiders thus, in some cases where it is necessary, are able to counteract the effect of the methods of ill-advised grownups in the home.

### Correction

Through an unfortunate typographical error appearing in the concluding sentence of the article by Dr. Alexander Lambert on "The Attitude of the Physician to the Health Center," page 641, December issue of *THE NATION'S HEALTH*, he was credited as saying that "rural standards should be lower." Dr. Lambert's statement was that "rural standards should *not* be lowered."

Keystone View Company.

The fairy stories told the children at bedtime must carry no gruesome content that would tend to promote a persistent and devastating fear repression to become operative under the stress and strain of adult life.

# Will Making and Community Welfare

## Interests of Communities and of Individuals Advanced Through Thoughtful Planning of Estates

BY WILLIAM T. CROSS, CHICAGO TRUST COMPANY, CHICAGO, ILLINOIS

THE possibilities of use and distribution of one's accumulated property as a means of attaining his desires and of assisting others under the complex conditions affecting private fortunes, is suggested in recent action by the Chicago Trust Company. This institution has established a consultation service in its Trust Department, which is designed to assist patrons of the bank and others in planning the management and distribution of their property. All banks and trust companies, as is well known, are sources of advice regarding property transactions. Whatever importance attaches to the provisions made by the institution mentioned lies in the degree of specialization of service provided and in the recognition given to the human problems that underlie the brief instruments by which men pass-on control of their fortunes. The arrangement calls attention to the significance of bequests and inheritances in relation to community welfare, and to the social content of such terms as guardian, trustee, executor, agent, beneficiary.

Eight thousand eight hundred fifty-five estates were filed for probate in Cook County, Illinois, during the year 1920, an area for which the United States Census reports a population of 3,053,017. Inheritance taxes were paid on 823 estates during that year, this being approximately 10 per cent of the number of estates probated. One-fourth of eight thousand estates probated in a recent year in Cook County, according to one authority, were covered by wills. The remaining six thousand estates were distributed to children and other heirs, following the fixed plan of the Illinois law. For the year 1918 the Chicago *Daily News* reports gifts to charity under the wills of five Chicagoans amounting to \$4,805,000. Further than this, no report is available as to the amount of philanthropic gifts under the two thousand or more wills probated. Where there was no will, nothing went to charity.

These meager figures, while incomplete, may be considered representative and carry the suggestion of what the community might gain through

*If the greatest amount of service is to be rendered through bequests for social welfare or for the care of the sick, will makers or their advisers must be somewhat expert in determining types of work to be aided, the extent of aid that is useful, and the most effective ways of safeguarding the purposes of the bequest.*

*For the welfare of the individual beneficiary, careful provision should be made through wise restrictions and against unwise ones, and for safeguarding the individual trust. The stakes at issue are important to individuals and communities. Although only slightly discussed heretofore, organized efforts for greater efficiency should be encouraged by all who have an individual or a community interest at stake.*

wider appreciation of the importance of having wills and through regular consultation on the part of all those who write wills as to the possibilities of conserving their estates and using them to advantage.

An influence in this direction has resulted from tax legislation. Many men face the alternative of giving either to charity or to the government. Possessors of fortunes above

fifty thousand dollars have their attention brought pointedly to the advantages of putting their estates more directly in the service of others, either through immediate gift or by creating trust funds to be administered on behalf of those they wish to assist. In the accompanying chart there is presented a graphical illustration of the acceleration of the tax rate on incomes and inheritances.

Both below and above the point at which tax rates begin to tell, there is need of thoughtful planning. Nearly every family, in the course of a generation, is affected by the inheritance of property. Many estates are of only small value, to be sure. The effective use of small accumulations, however, is vital to both giver and recipient, and the processes and pitfalls should be understood by them as well as by the more fortunately situated.

A few years of educational publicity of the type that is being furthered by the Trust Company Section of the American Bankers' Association may be expected to bring about a better understanding of the opportunities afforded in passing on estates. The attitude at present may be compared with ideas that were prevalent regarding life insurance a generation ago, or regarding vocational training twenty years ago.

The same forethought and analysis that lead a man to buy insurance or to plan a vocational future for his children will lead him to organize his

INCREASE IN PERCENTAGE OF INCOME AND INHERITANCE TAXES (AS SIZE OF ESTATE AND OF INCOME INCREASE).

Net income used as basis. In computing inheritance tax, a standard situation is taken in which the estate descends to one near relative. State and Federal taxes are combined.

estate effectively for handing-on, once the procedure is clear to him. Wills now are prepared hastily, or over-ceremoniously, or with a sense of impending death. Men are concerned more immediately with getting on financially. They have in mind vaguely that in the end the bulk of their holdings will go to those for whom they have been responsible in life. They do not in many instances calculate the ways in which their fortunes may be utilized by their heirs or the effects of leaving no wills. The possibilities of trust funds, or of other plans for shaping estates for effective use with beneficiaries or charities are often unthought of. Yet

tal. This suggests that the donor may have been poorly informed as to needs, and further that the terms of his will may have been ambiguous.

### III

The Sarah Morris Hospital for Children, established in Chicago in connection with the Michael Reese Hospital, was provided in 1910 from a fund of three hundred thousand dollars left by Mrs. Morris. She had been a supporter of the hospital for years, having given, altogether, \$250,000 toward its maintenance. The bequest in her will was made to her children with the instruction that they should determine a suitable object. The trustees of the Michael Reese Hospital agreed in furtherance of the plan to provide maintenance for a 125 bed hospital. This is done

Sarah Morris Hospital for Children is one of the most attractive medical foundations in Chicago. It was built in connection with Michael Reese Hospital under a liberal agreement whereby the children of the donor were given authority to determine the object to which the funds should be devoted.

in the disposition one makes of his property after his direct control over it ceases in many instances a man has his greatest opportunity for use of financial capacity and for careful judgment of human relations.

The value of expert guidance in planning charitable bequests is suggested in the references to wills that follow:

#### I

A bequest has been made recently, in a large city, for the establishment of a children's hospital. An attorney, as trustee of the fund, has gone abroad to study plans, closing up his law practice to do so. Had the donor taken the community more into his confidence, or were there less individuality in the initiation of the plan, the benefits to the community might be more direct and substantial.

#### II

In the same city, a bequest for establishing a maternity hospital for persons of moderate means has been used eventually for a general hospi-

through cooperation of the Associated Jewish Charities.

#### IV

One of the most influential series of gifts and bequests for public purposes in Chicago is that of the late Marshall Field. Near the end of the World's Fair in 1893, he provided by donation one million dollars to secure the establishment of the Field Columbian Museum, to which were given many exhibits from the Exposition. Other Chicago citizens gave substantial amounts and also art collections. About two hundred thousand dollars were received through contributions by more than one thousand citizens of their stock in the Exposition Company. The original donation of one million dollars was

Lucius Teter, president of Chicago Trust Company, has served for ten years as head of the Infant Welfare Society of Chicago. He was until recently president of the Chicago Council of Social Agencies, and is a former president of the Chicago Association of Commerce.

made on condition that \$500,000 additional should be provided by other donors. The same principle was applied by Mr. Field in his will, under which four million dollars was given for a new building, and four million dollars additional for endowment, maintenance and extension of collections of the Museum and for administration. This was conditioned upon the provision of a building site from other sources. The new building that has been erected recently on the lake front

Entrance to Chicago Trust Company at State and Madison Streets, the "busiest street corner in the world."

A conference room, where patrons may discuss confidentially the future disposition of their estates.

in Grant Park affords an example of the relation of one benefaction to another. Near the Museum may soon be located, according to the arrangement of the Chicago Plan Commission, a stadium that will seat one hundred thousand persons. Mr. Field in his will provided also endowment funds for an orphan asylum, an old people's home and two hospitals.

#### V

Bryan Mullanphy of St. Louis in 1851 left a fund the income of which was to be used perpetually to aid immigrants going westward in crossing the "Great American Desert." That was in the days of the prairie schooner and of unconquered Indian tribes.

#### VI

A trust is reported to have been established in Cleveland recently, the income of the fund to be used perpetually, in designated amounts, for the support of specified institutions. The question of their efficiency in subsequent years, or their comparative value in a rapidly growing community, was not taken into account.

#### Two Wills in Contrast

The man who has a sort of "city plan" for his estate and who understands the more economical ways of passing-on property is apt to be of more assistance both to his immediate relatives and friends, and to the charitable interests of his community. The possibilities of well calculated action in bequeathing property are illustrated in the plans of two wills that have come recently to the attention of Chicago Trust Company:

#### VII

*Pattern of Mr. Heath's Will.* The bulk of the estate is kept intact and efficient administration is assured through naming a trust company as co-executor and co-trustee with the wife. All property is put in two trust funds for support of the wife and one child, a daughter, with the exception of specific bequests made to five charities, and one-third of the remaining estate that is given outright to the wife. The daughter acquires ownership of her portion at thirty years of age, and of her mother's portion when

the latter dies. The language is simple and intention unmistakable. Various contingencies are provided for, such as decease of daughter before reaching thirty years of age. It is the will of an experienced and capable business man.

#### VIII

*Pattern of Dr. Jenkins' Will.*—Numerous special gifts are made, constituting a large proportion of the estate, with evidences of sentiment—as, for example, "two hundred dollars and first choice of fifty books from my library." Residuary estate left to wife, and no arrangement made for trust fund for either her or a daughter, who is given a specific bequest.

No gifts to charity. The property was of such nature that a long period was required for liquidation in order to avoid losses. Bequeathing property was, to this man, a sentimental ceremony, little thought being given to conservation of an estate in the interest of his beneficiaries.

The desires of these two individuals may have been fundamentally the same. Although the situations of their prospective heirs were somewhat dissimilar, it is evident that those in the first example were treated more advantageously. The second man bequeathed his estate in such condition that his executor had difficulty in managing it and finally asked a trust company to take over the work as his agent. Liquidation required an unusually long period and, as a consequence, some of the beneficiaries got little satisfaction from his beneficence. Advice about effective methods of passing-on property, by will, might have led the second man to put his affairs in shape for the purpose, perhaps through a trust established during his lifetime, and to arrange his bequests more effectively. It is noteworthy that the second man, although he was the more

The Trust Department of Chicago Trust Company, where the details of fiduciary business are handled.

religiously trained, had no place in his plan of bequests for public charity. Not only are wills to be distinguished as being effective or ineffective instruments in achieving the purposes of those who write them, but among the good ones various plans of bequest may be followed, according to the testator's ideas of using property.

Social and economic perspective needs to be brought to bear on the establishment of foundations and on the disposition of private fortunes in order to assure the would-be benefactor of the permanent values of the ends sought and to insure execution of plans. A service is inestimably important that makes available information on the practical workings of various plans of bequest and philanthropy and that searches out the various sources to which interested persons may be referred for supplementary information. Those who have not written wills or whose wills do not suit their present situations are encouraged to take advantage of this service and to provide themselves with satisfactory plans without delay, as a matter of insurance and as an ordinary business procedure.

Field Museum and proposed stadium in Grant Park, Chicago. The stadium will be the largest in the world and will seat one hundred thousand. The Museum began with a series of contributions headed by the late Marshall Field, at the time of the World's Fair in 1893. It shows the possibility of subsequent combination of civic improvements if a bequest is made for a public purpose and is worded liberally.

# Cardiac Diseases in Adolescents and Adults

## The Incompetent Heart as a Sequel to Preventable Infection is a Serious Public Health Problem

By LOUIS I. HARRIS, M.D., DR.P.H., DIRECTOR, BUREAU OF PREVENTABLE DISEASES, DEPARTMENT OF HEALTH, NEW YORK CITY

THE prevention of diseases of the heart and of the circulatory system has only comparatively recently begun to claim its share of attention. In the din of voices of the many advocates of this and of that public health measure, the plea of those who would focus attention upon the necessity of efforts to prevent cardiac diseases has been nearly lost.

The emotions and sentiments of people cannot be so readily stirred by an appeal for the prevention of cardiac diseases. To the average healthy person, the danger of heart disease seems so remote, and the nature of such disease is so mysterious and confusing, that it is hard to win popular sympathy and support for an organized effort to prevent heart diseases. To those who have not come face to face, in the home or through social or medical work, with the havoc wrought by diseases of the heart there is a lack of the dramatic and popular elements such as have won interest for other phases of public health work.

Diseases of the heart in adults very frequently produce serious secondary changes in the arterial system of the body as a whole, or in localized areas such as in the kidney or brain; or, conversely, such cardiac diseases are secondary to diseases of the circulatory system or kidneys. There is, therefore, a very definite and intimate correlation between diseases of the heart, blood vessels, and kidneys. This is so close a relationship that one cannot entirely separate them in a consideration of a preventive program.

### Show Appreciable Increase

Statisticians have disagreed as to whether or not diseases of the heart and of the circulatory system as a whole have increased during the past several decades. Making allowances for the fact that the registration of the causes of death has become more accurate, and that many deaths which we now recognize as being due to cardiac affections were formerly ascribed to "senility," "dropsy," or "sudden death," or were so reported

*While records, as pooled by thirty-seven life insurance companies and reported recently in New York, show 1921 to have been the healthiest year in the history of the United States and Canada, certain causes of death—among them organic disease of the heart—have shown appreciable increase.*

*It is a blot upon our public health records that so great an aggregate of disability should result from preventable infections or from conditions so open to social correctives.*

*A health program is self-limited which does not take early account of predisposing conditions. Especially should preventive medicine search out and protect the great army of chronic cardiacs.*

that the cardiac diseases were wrongly subordinated to some incidental or terminal disease, it seems nevertheless to be true that there has been a definite and appreciable increase in the prevalence of these diseases. However, putting this question aside for the time being, the fact cannot be gainsaid that a great multitude of persons in various age groups are afflicted with such disease. This we are able to state despite the fact that our morbidity statistics are so woefully deficient and unsatisfactory. If it were possible to summon to some central gathering place every person in the United States in whom cardiac disease was definitely diagnosed, even under the limitations which at present hamper our recognition and discovery of all cases, we would bring together enough persons with cardiac disease to equal or possibly outnumber the population of the city of Chicago, the second largest city in this country. If we were to add to this number the persons in this country who suffer from arteriosclerosis or from chronic renal disease, it would be fair to assume that we would have a cardio-nephritic pop-

ulation larger in size than that of the city of New York, which is now estimated at 5,753,151.

In his article on the "Incidence of Heart Disease in Adults," Dr. Dublin very aptly introduces the evidence which he has to present pointing to an increase in the prevalence of organic heart disease by the following statement:

There are today two outstanding public health problems in America, namely, tuberculosis and heart disease. Both are responsible for about the same amount of sickness and death. There are about two million persons in the United States who are seriously impaired from heart disease, and also from pulmonary tuberculosis, and approximately one hundred and fifty thousand of them die each year from each of these two causes. These two fields of public health work have been very differently exploited. That of tuberculosis has for over a period of thirty years received the greatest public attention.

In fact, a recently published report of the Framingham Demonstration gives evidence tending to show that 1 per cent of the population is suffering from active tuberculosis, whereas, in the course of this article Dublin shows that 2 per cent of the persons examined by the insurance companies are rejected each year because of a variety of organic heart defects. Dr. F. L. Hoffmann reports similarly that another company has rejected 2.4 per cent of applicants for insurance because of cardiac defects. There are no available records of a satisfactory character which would conclusively show the frequency of heart disease in the general population, but there have been a number of individual studies which are extremely illuminating.

In connection with the examination of men who were drafted into military service in the recent war, it was reported that of 2,400,000 examined, 120,000, or 5 per cent, showed organic cardiac defects. As a result of the checking up of these cases by the medical members of the advisory boards and by special experts in the diagnosis of cardiac diseases, the cardiac defects were reduced to 85,143. In these the defects were of sufficient

gravity to cause the rejection of the men from military service. In other words, 2.62 per cent or 26.26 men per thousand, of military age, were found to be affected with organic heart disease. In addition there were 3,172 men who were suffering from mitral insufficiency or mitral stenosis with adequate compensation who were accepted for limited military service.

It is interesting to note that many of the reports which have been made on this subject show that the prevalence of cardiac defects among persons living in rural communities is less than among persons living in urban communities, although the incidence of heart disease among those engaged in farm labor is comparatively high. The rate of prevalence of cardiac defects has by some observers been shown to vary according to geographic location, but these conclusions are not to be accepted, because of the marked difference in the diagnostic facilities existing in respective communities as well as because of deficiencies in the methods of health-bookkeeping which prevail. It has been noted, for instance, that in Ireland and Italy, the incidence of heart disease at various ages is higher than in most other countries, and that there is a marked difference in incidence between various parts of the United States. This observation must be accepted with great reservation.

It has also been observed that females show a greater incidence of cardiac defects up to the age of twenty-four years than is found in males of similar age groups. After twenty-four years, however, the incidence of cardiac defects becomes increasingly pronounced in males.

### The Heart as a Handicap

The rôle which heart diseases have played in causing poverty and adversely affecting the lives of entire families because of the crippling of the wage earners, is difficult to estimate, but it no doubt constitutes a very substantial and serious factor in the social lives not only of the several million sufferers from these diseases, but among their many dependents as well. Practically every age group of the colored population is affected more heavily than are the whites by organic cardiac disease.

The studies of Schereschewsky and of Robinson and Wilson of the United States Public Health Service among garment workers and among employees in various industries in Cincinnati, respectively, have also given evidence that the rate of prevalence

of organic heart disease among the general groups of the population is about the same as was found in those who were examined in the draft.

The study made by the author in association with Dr. Dublin of the Metropolitan Life Insurance Company among a group of 1,980 food-handlers who were submitted to a particularly careful examination, showed a larger incidence of organic heart disease than has generally been reported. We found a fairly high percentage of organic disease among the bakers, waiters, and cooks who were the subject of our investigation. This study as well as the incidence and mortality rate in cardiac diseases in various occupations suggests the necessity of more intensive study of a number of occupational groups who are particularly subject to industrial hazards. It may be stated with assurance that such special occupational studies would reveal a very much higher percentage of cardiac defects in a number of industries than was found to prevail among insurance applicants or men between twenty and thirty-one years of age drafted into military service. We have fairly definite evidence that men employed in the iron and steel mills, especially when their work brings them in close proximity to the various types of furnaces, or processes which subject them for comparatively long periods to temperatures ranging from 100 degrees to 130 degrees F., and are in some cases exposed for brief periods and at fairly frequent intervals to temperatures ranging from 200 degrees to 220 degrees F., that the incidence of myocarditis must be very great. Several observers have reported sudden deaths among such steel workers while at work as the result of organic cardiac disease. It would be of great value also to learn more about the prevalence of organic disease among stationery firemen, ship's stokers, and others similarly employed, as well as to differentiate from among the great mass who are commonly designated as "laborers," so to distinguish the relation of physical strain or exposure to excessive heat, and other factors present in such occupations, to the development of organic heart disease.

### Incidence by Age Groups

Interest attaches to the classification by age groups of organic heart disease cases treated in the Glasgow Hospital in 1909. While this does not give the rate of incidence per population, it is interesting to note how the 1,346 cases of heart disease which

required hospital care were at the time divided according to age groups. It has certain social and economic implications which are of definite interest.

TABLE 1.—MORBIDITY—GLASGOW HOSPITAL—ORGANIC HEART DISEASE, (1909).

Age groups	Cases treated
Under 10.....	20
10-20.....	221
20-30.....	264
30-40.....	274
40-50.....	257
50-60.....	186
Over 60.....	124
Total.....	1,346

Dr. Dublin in his report of the "Cause of Death by Occupation," published by the United States Department of Labor for the year 1911 and 1913, gives an analysis of the causes of death among insured persons according to occupation which tends to show that certain occupations are particularly hazardous. He singles out for special emphasis, farmers, blacksmiths, laborers, and masons. In still other studies that have been made, other occupational groups have been shown to have a conspicuously high mortality rate at comparatively early ages as the result of organic heart disease, such as garment workers and bookkeepers.

Unfortunately, it has been customary to concentrate attention almost exclusively on at least largely upon the number of deaths from cardiac diseases. Owing to the lack of dependable morbidity statistics, we know very little about the degree to which cardiac diseases unfit men and women for work and create invalidism. The lack of fitness for the enjoyment of normal life, and total incapacity which undoubtedly exists in thousands of cases by reasons of these diseases, must not be overlooked.

### Diseases Affecting the Heart

We know definitely that heart diseases result from focal infections, also from the various infections diseases, particularly those of childhood, as well as from perverted functioning of various organs of internal secretions, and from over-functioning of the thyroid gland, which is particularly important in adolescent girls. Cardiac and arterial diseases are most intimately related to syphilitic infection, and this is important to bear in mind as a possible explanation of the marked prevalence of cardiac defects among certain social groups, and may also explain, in a measure, the fact that for certain age groups, the rate of prevalence of organic heart disease among the colored people is almost twice as high as for

white persons of similar age groups. It is to be noted that the susceptibility of the colored race to a variety of infectious diseases to which they have been exposed in the last two centuries in particular has as its basis, no doubt, the lack of racial immunity, due to a comparatively limited period of contact with such diseases. To this fragmentary enumeration of some of the commoner causes of organic heart disease, one should add a variety of toxic agents incident to faulty metabolism or to lack of care as to personal hygiene. Also toxic agents arising as a result of various diseases as well as those that occur in the industrial environment must be included as potent factors. Long continued physical strains also belong to this category. In an indirect way mental and nervous strains, excesses of various kinds, as well as other factors in the home or industry which induce fatigue may act as indirect causes of cardiac disease. These are among the more familiar causes of cardiac disease, and probably for that reason they have been treated with indifference on the part of the public.

Every clinician who has had experience in the care of persons suffering from diphtheria and scarlet fever has seen the beginning and the evolution of heart disease in many such individuals. Frequently, too, the clinicians can definitely mark the date when follicular tonsillitis or some other infectious disease has inaugurated a pathological process which dooms the patient to suffering, to incapacity, and very frequently to an early death. Physicians, by and large, have been given little opportunity to study the effects of the less obvious factors in the production and evolution of cardiac defects. They have left to private initiative and to commercialized philanthropy the opportunity to make periodic health examinations of their patients, to discover, and to check incipient organic defects.

What we are particularly concerned about as a public health problem, is the early recognition of cases in which any one of numerous causes may have operated to produce damage upon any part of the heart or the vascular system, so that we may shield such persons from physical and mental strains so far as possible, and to prevent their exposure to subsequent infections.

To put it differently, there are several types and stages of preventive work. To begin at the beginning, in order to prevent diseases of the heart,

there ought to be care on the part of those who enter into matrimony that in the interest of future offspring, each of the contracting party should be free from syphilitic infection. In the absence of more definite knowledge as to the inheritance of gouty, or other metabolic or endocrine defects, we cannot include these with syphilis as transmissible conditions which may have a definite relation to the development of heart disease in offspring.

Next we come to the period of infancy in which the community as a whole—parents, public health officials, and school authorities—have a definite and individual moral and legal responsibility for protecting children by providing proper housing, ventilation, etc., so as to shield them against contracting infectious diseases and being exposed to other influences or conditions which may lay the foundation for serious cardiac disturbances in the future. The pre-school age group of children have not as yet the benefit of an organized protective agency. It is not the province of this paper to dwell upon the efforts to protect child life in general. Much that is most excellent has already been done in this field.

For adolescents, there ought to be ample provision to ascertain whether or not a given child may be suffering from a cardiac defect, or a condition conducive to such defects, and if so, to make certain that such children are not permitted to enter into industries in which they are inevitably doomed to suffer an aggravation of their cardiac disease with all the menace to health and to life which is implied. Such adolescents should not be permitted to be employed in an industrial environment in which excessive heat, physical strain, or other causes of fatigue may operate alone or in conjunction with other factors to cause a cardiac breakdown. Vocational guidance in this connection does not merely mean a study of the mental and physical endowments of these adolescents with respect to their adaptability to certain occupations, but it should be definitely continued by a studious regard on the part of health officials to so supervise industrial establishments and conditions of work as to prevent any untoward reaction of such occupation upon the heart and physical capacity of such children. This is not dictated by any paternalistic theory, but is a policy which is economically sound and humane.

It may be interesting to note that during the year 1920, of 51,097 chil-

dren who presented themselves for working papers to the Bureau of Child Hygiene, Department of Health, 813 or 1.6 per cent were found to have a cardiac defect. No doubt, in these examinations, as in most of the examinations conducted by physicians, hospitals, and dispensaries generally, the more modern instruments of precision if they had been available, would have made possible the recognition of even more children having a beginning pathological condition of the heart which could not be detected by the ordinary methods of examination. The law gives the Health Department the power to defer the entrance into industry of those like these 813 who presented cardiac defects among the applicants for working papers last year. At present, however, all control, such as it is, over these defective applicants for employment, is lost when they are sixteen years of age, and the oversight of sanitary health conditions in the shops and factories to which their entrance has been to a great degree neglected.

The time may not be far distant when some organization having a keen regard for the sanctity as well as the economic value of human life will carefully censor each case of death reported in a community and place the blame for such death upon the public authorities, parents, or employers, each in proper measure, as they may have been responsible for failure to conserve and prolong the lives of those who are exposed to the development of cardiac disease or already so handicapped. Many despite themselves, live in overcrowded quarters, or are exposed to the danger of infection as the result of conditions of living or work. Because of neglect of officials or parents to correct potentially dangerous physical defects, they may be thrown into the human scrap heap prematurely like so much discarded and useless machinery. Such a body of censors could rouse those who are responsible for tolerating conditions that are preventable, to a sense of their guilt as passive or even as active agents, by bringing specific indictments for the preventable deaths which occur in the community.

From an economical as well as from a humane and sentimental viewpoint, the lives of infants and young children should be most solicitously guarded. So far as adults are concerned there has, however, been a reflection of a too intensely economical and materialistic viewpoint, in the indifference which, by and large,

exists with reference to the need of similar intensive methods for conserving the lives of such adults in the various age groups. We have been too much obsessed with the estimation in dollars and cents of the life value of adults who die from cardiac as well as other diseases. The reduction of infant mortality, which has been marked by the awakening of some communities to an appreciation of the needless sacrifice of such infants which some years ago was tolerated with indifference or stoicism, has been a cheering sign of the times; but it is necessary to arouse many to an understanding, that through preventable diseases, among which organic heart diseases are conspicuous, we lose annually in this country a small army of young adults whose loss not only brings sorrow and suffering into many homes, but deprives the community of persons capable of making most valuable, social, cultural as well as material contributions to their fellows and to society as a whole. The same commendable impulse which has already achieved such wonderful results in the conservation of child life, must be stimulated and sustained with respect to the prevention of cardiac diseases.

Sufficient emphasis has not been given to the fact that early diagnosis of pathological conditions in the heart is most urgently needed to protect individuals not only from physical and other forms of strain and exposure to danger which are familiarly recognized, but that those suffering from organic heart defects cause a very decided increase in the number of fatalities which are attributed to childbirth, surgical operations, intercurrent infections or other diseases. In other words, mortality from cardiac disease is increased because the affected individuals are not able to meet the normal stresses and strains of life, or certain critical conditions which in a person having a normal heart would not terminate fatally in the large majority of instances. In other words, a person with organic cardiac disease in whatever age group found, suffers a handicap which adds appreciably to the mortality rate from a variety of relatively minor surgical and medical diseases. If all cases in which cardiac defects are a joint factor in the cause of death, or a determining factor, and where some other cause of death is given, were added together, the total of organic heart disease would assume a more serious aspect than is shown in our present statistics.

TABLE II.—DEATHS, UNITED STATES CENSUS AREA, 1918

	Heart Disease	Bright's Disease	Apoplexy	Total
Under 1	630	173	188	991
1	177	133	69	379
2	111	98	42	254
3	111	81	13	205

100 and over	79	50	33	162
Unknown age	222	122	112	456
Total	124,514	73,239	68,861	263,614

Without attempting to adduce further statistical evidence of the prevalence of cardiac diseases in our community, enough has been presented by numerous writers upon this subject, whose voices have thus far fallen upon deaf ears, to indicate the necessity for an aggressive and organized attempt on the part of each and every public and private agency which has a duty or interest in the matter, to apply preventive measures which are appropriate to meet the problems of preventing cardiac diseases at the various stages of life briefly alluded to in the foregoing section.

Before proceeding further to outline with somewhat greater definiteness a plan of campaign to cope with the menace of cardiac diseases, reference should, however, be made to other fragments of evidence showing whether or not cardiac and the related diseases have increased. They are at any rate one of the most conspicuous causes of death in every community.

A table is appended showing the mortality from heart diseases in that area of the census in which public-health bookkeeping has been maintained and which is known as the "registration area." It will be seen that the death rate per hundred thousand from various forms of heart disease, has by and large shown a substantial increase during the period from 1900 to 1918. In 1918, the deaths from influenza claimed a host of victims in this country—it probably caused about three-quarters of a million fatalities—and was in a measure at least responsible for the seeming decrease in the incidence and mortality rate of tuberculosis, heart disease, and other diseases.

TABLE III.—MORTALITY FROM HEART DISEASE—UNITED STATES REGISTRATION AREA, 1900-1918.

*Death Rates per Hundred Thousand of Population*

	All forms of heart disease	Organic heart disease
1900	131.9	111.1
1905	152.1	131.2
1910	158.8	141.5
1915	165.1	147.1
1916	168.0	150.1
1917	170.9	153.1
1918	169.0	152.3

TABLE IV.—DEATHS—NEW YORK CITY, 1920

	Heart Disease	Bright's Disease	Apoplexy	Total
Under 10	219	28	7	254
10 to 19	361	51	3	415
20 to 29	378	125	6	509
30 to 39	664	277	21	962
40 to 49	1,243	567	67	1,877
50 to 59	2,181	960	128	3,269
60 to 69	2,796	1,200	208	4,204
70 to 79	2,383	950	185	3,518
80 plus	1,117	418	93	1,628
Total	11,342	4,576	718	16,636

Space does not permit the presentation of statistical evidence showing that there has been not only an increasing mortality from organic heart disease, but an increasing number of deaths registered at an earlier age than in former years.

### Surveys Nursing Service

A survey of nursing service in one hundred industries in Massachusetts was reported in a paper read at the November meeting of the New England Industrial Nurses Association by Mrs. Anna M. Staebler, who made the survey as Executive Secretary of the Massachusetts Committee on Health in Industry.

# Medical Development of China Receives Impetus

## A Study in Contrasts on the Basis of Public Concern Regarding Health Conditions

BY EDWIN R. EMBREE, SECRETARY, ROCKEFELLER FOUNDATION, NEW YORK CITY

IF ANYONE doubts the value of medicine and its application to the health of the people he should visit such a country as China and see the appalling results of the lack of scientific attention to public health. Smallpox patients, with disease in active stage, are about the streets; typhoid fever, which is being eliminated in the West by sanitation of water and milk supplies, is rampant; blindness, trachoma, and other diseases of the eye are everywhere in evidence on the city streets; the infant mortality is shocking; anemia, resulting from hookworm and other intestinal parasites, seems to be well nigh universal. No one who has not seen the disease, suffering, and death among a people who neglect public health can realize the tremendous advance that has been made in America and Europe through diligent, painstaking, and scientific efforts towards the control of disease.

The progress of medicine in China is marked by three distinct stages: (1) Medical care by foreigners, chiefly medical missionaries, in the form of small hospitals and dispen-

saries attached to trading companies and through medical missionaries. In the year 1805 Dr. Alexander Pearson, surgeon to the East India Company, introduced vaccination in China; in 1820 Robert Morrison and Dr. Livingston of the same company opened temporarily in Canton a dispensary, dealing chiefly in Chinese drugs, and in 1827 Dr. Thomas Richardson Colledge at the port of Macao founded the first permanent institution in China for the purpose of bringing the benefits of western medicine to the suffering Chinese, the Macao Ophthalmic Hospital.

Peter Parker, a Yale graduate and representative of the vigorous Yale Mission Board of those days, the first medical missionary ever appointed as such by any mission board, began in 1834 the great work under missionary auspices which for three-quarters of a century gave to China most of its medical service.

The medical missionaries began from the first to develop hospital facilities. With small resources and with scant equipment they renovated houses, put in beds, accepted patients,

dividual patients; they have served also as centers from which have radiated knowledge of western medicine, respect for modern science and the beginnings of appreciation of public health.

The second step in the development of medicine in China has been the establishment of medical institutions of high standard for the training of Chinese physicians, nurses and technicians. For many years a few Chinese have been studying in other countries. A number have been trained in America, and small groups in England and the countries of Continental Europe. The chief place for foreign education, however, has been Japan. Unfortunately, on account of language and other limitations, the Chinese have found it difficult to enter the great Imperial Universities of Japan. Trained at the inferior special schools, the Chinese physicians, who are largely in charge of government positions in army and provincial and municipal posts, do not represent the best in Japanese education.

Study in foreign countries cannot

This admirable institution, erected and managed by Chinese initiative and with Chinese funds and staffed with Chinese personnel, represents the most encouraging evidence of the application of scientific medicine and of modern methods by the Chinese themselves.

saries dotted here and there throughout the country; (2) the development of medical institutions for the training of Chinese physicians; and (3) the beginnings of Chinese control of their own medical and health work as trained Chinese personnel and leadership evolve.

The earliest infiltration of western medicine came through the physicians

and gave such medical and nursing care as they and their families could offer. Catholics and Protestant alike have fostered this scientific and humanitarian work. At present between two and three hundred mission hospitals are scattered throughout practically every province of the immense country. Not only have these institutions given medical relief to in-

solve the problems of a nation's education in any art or science. The establishment of medical schools in China has therefore been regarded as the most important aspect of the direct contribution of the West to this great country of the East. The Hunan-Yale School at Changsha, Central China, the former Harvard Medical School at Shanghai, and the Med-

ical Department of the Shantung Christian University at Tsinan have been for a decade giving a creditable

to medicine. Nearby in the Tartar City are situated in two residence areas groups of modern brick houses

alive. Few medical schools, few faculties, have ever had before them the opportunities or the challenge to high endeavor which now confront the Peking Union Medical College.

Ward in Central Hospital, Peking. This arrangement, light, and ventilation in this Chinese hospital, erected and directed entirely by Chinese, are beyond criticism. The medical and nursing care is of high standard.

medical training to ever increasing numbers of Chinese.

### Peking Medical College

The latest addition to the forces of medical education in China is the Peking Union Medical College. This institution, founded on the basis of an earlier school organized under a union of American and British missionary societies, has been taken over by a group of Trustees representing jointly these original societies and the Rockefeller Foundation. An entirely new institution including modern laboratories and ward buildings has been erected and is being maintained by funds from the China Medical Board of the Rockefeller Foundation.

The Peking Union Medical College was formally dedicated to its service to medicine in China in the autumn of 1921. At the time of the dedication there were held in Peking meetings of the Trustees of the college and an international medical congress including representative men of science and educational leaders from France, the British Isles, America, Canada, Japan, Java, the Philippines, Korea, and practically every province of China.

### An Interesting Group

The new college has been in course of construction since 1917. Sixteen buildings, with sweeping green tile roofs and great overhanging eaves house the laboratories, hospital wards, and auxiliary structures of the institution proper. Adjoining are the buildings of the pre-medical school which gives three years of intensive training in the chemical, physical, and biological sciences preparatory

—the homes of the members of the faculty and their families. The institution has been erected in architecture characteristic of the best in Chinese classic and sacred building. It is maintained in accordance with high standards of western science.

It is recognized that neither this institution nor any number of schools which one agency might maintain would be able to train the great body of medical practitioners needed by the Chinese. The purpose, therefore, in establishing this college has been to set standards, to train leaders, to demonstrate what an adequate medical college in China might represent. Thus, by a single institution, it is hoped to influence an entire nation. It is because of this purpose that so great significance was attached to the attendance at the dedication last autumn of the large body of medical men from all parts of China, and to their expressed desire to share in the opportunities for cooperation and for advanced study.

### Looks to Future

The budgets provided for the college and hospital for the years of the immediate future, while slightly below those of similar well-established institutions of high standing in the United States, are so much above those of the other colleges and hospitals in the Chinese republic as to make this institution unique in all China, in some aspects unique in the entire Far East. This places upon the faculty a responsibility for leadership in medical teaching, in nurse training, in hospital management and in the advancement of medical science and public health, to which they are

### Personnel and Leadership

Finally, and most encouraging of all, the Chinese through their own leaders and their own trained personnel are beginning to organize and to man their own hospitals and to make beginnings in the establishment of their own medical schools. The most farsighted of the education leaders from the West have recognized from the beginning that only by developing Chinese personnel and Chinese initiative could the medical problems of this great country be met. The new medical college at Peking, the Hunan-Yale school at Changsha, and similar institutions have had as a major purpose the development as rapidly as possible of Chinese scientists who would begin to take the responsible position in teaching and in management.

### An Outstanding Work

The Central Hospital in Peking is a most encouraging example of the present stage of development. The Central Hospital was erected by Chinese funds as a result of Chinese initiative; it is maintained by a Chinese Board of Trustees and supported by contributions from the Chinese. It is a striking instance of the fulfillment of Chinese promise in medical science and medical service.

Section of the great wall of China. This wall is a symbol of the "closed door" which China maintained for centuries and which kept out friend and foe alike. Only recently are new ideas and modern science beginning to transform the ancient and great people.

An interesting adaptation of sheet iron construction in the dispensary at Wuhu on the Yangtse River.

To such men as Dr. S. P. Chen, the director of this hospital, Dr. Fu-chun Yen, dean of the medical school at

Changsha and a small group of men is now being handed the torch of medical leadership in China.

## English School Health Program

BY OUR LONDON CORRESPONDENT

THE annual report of Sir George Newman, chief medical officer of the Board of Education, has been issued recently. The national system of inspection was established in 1907, and although the war delayed its proper working, good results are beginning to manifest themselves. While the scheme as a whole has abundantly justified itself, only a part of the problem is covered. As the report points out, in order that it be really effective, it must be extended to both the years preceding and the years following school life. However, the lack is being increasingly supplied, and the ideal of coordinated supervision is being approached in an endeavor to arrive at a sound and practical training of the body from infancy to adolescence.

Such supervision is not a waste of money, as some contend, but a step in the direction of economy, the report declared. For instance, last year's medical inspection showed that of 2,434,252 children examined, 1,166,794, or 47.9 per cent. were found to be suffering from defects. The report states that the medical staff of the 316 local education authorities numbers 800 whole time officers or thereabouts and 1,900 school nurses. In round numbers, 2,400,000 children are medically inspected during the year, falling into three groups at five years, eight years, and at twelve years,—in other words as entrants, intermediates, and leavers. Each child whether sick or well attending the public elementary schools passes medical inspection at the hands of a

doctor three times in his school life.

There are some good school clinics used partly for examination purposes but mainly for treatment. The experience of the education authorities during the past fourteen years has demonstrated, first, that there is a degree of physical defect and impairment among school children which prevents large numbers of them from receiving reasonable benefit from the education which the authorities provide, and is in itself wasteful in causing absence from school and disability; secondly, that unless the authority itself arranges for, or provides means of treatment, the great majority of children will not in fact be treated and a harvest of physical degeneration will result. It is superfluous to elaborate further, but this may be said, that, apart from all questions of suffering or disease or death, the State is not getting adequate returns for a substantial part of its public expenditure on education. If the child entering school is feeble or ailing, the system of public education is hampered from the beginning. The problem of securing the physique of the entrant is one of the serious problems of public health.

The physical welfare, and, in part, the education of the child of school age, are dependent in their issues upon ante-school conditions, healthy parentage, care of infancy, and a desirable home life of nurture. It is dependent upon its issues upon post-school conditions, after-care, continued physical education, supervision of juvenile employment, and some prac-

tical guidance in the duties of healthy and responsible parenthood.

The work of the sanitary authority and of the voluntary agency combined with general social improvement has brought about in recent years a decline in infant mortality which has effected since 1911 a saving of not less than 26,000 infant lives a year, the report states. The successful medical treatment of 400,000 school children in a year, a result of the school medical service, is an example of State economy. Something more is required, namely, the equipment of the child for life, its cleanliness, its physical training, its education, the preparation for and safeguarding of its future employment.

Three disadvantages of State intervention were anticipated in the early days: (1) that such action would pauperize the parent and destroy the sense of parental responsibility; (2) that it would impose an unremunerative burden on the rate payer and (3) that it would have a detrimental effect on the legitimate practice of medical men. The history of the school medical service has dispelled these fears. Parental responsibility has been stimulated, the investment is yielding high interest, and medical treatment has been sufficiently safeguarded to secure the support and cooperation of the medical profession.

### Rural Sociologists Meet

Prior to the first regular session of the American Sociological Society in Pittsburgh, rural sociologists held a session at the Fort Pitt Hotel, December 27, at 2:30 p. m. "The Rural Community and the Rural Neighborhood as Social Units" was the round table topic for discussion led by Dr. C. C. Taylor, North Carolina A. and M. College, Prof. J. H. Kolb, University of Wisconsin, and Prof. Dwight Sanderson, Cornell University. Dr. C. J. Galpin presided.

### "Children's Home" is Gift of New Yorkers

The Society for the Prevention of Cruelty to Children, a New York organization, is raising a \$4,000,000 building on Fifth avenue and 105th street, New York. The structure is the gift of Mr. and Mrs. August Heckscher who, approached with an appeal for a motor bus, responded with this generous endowment. The "Children's Society" was founded by Commodore Elbridge T. Gary and his associates.

# Motion Pictures as Used in Health Education

## Visualized Truth Carries Its Own Argument and Calls Forth Immediate Response

BY C. E. TURNER, ASSISTANT PROFESSOR OF BIOLOGY AND PUBLIC HEALTH, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, CAMBRIDGE, MASS.

THE production of motion pictures dealing with various phases of public health and sanitation is perhaps the most important development of the last few years in the field of popular health education. We are really just beginning to appreciate the educational possibilities of the "movie." And although the principle field of the motion picture may continue to be popular amusement, as it has been heretofore, the present attitude of educators in all parts of the country indicates that the motion picture, like the automobile, is likely to become an increasingly important and useful servant as well as a pleasing diversion.

### Hampered by Regulations

Several difficulties have delayed the development of an educational motion picture program. The amusement possibilities were so obvious and the financial return from this type of film so great that the available capital was diverted from the educational field, which required a more serious and less profitable form of production. The control of the industry has been mostly in the hands of men whose first consideration was financial return, and only recently has there been organized for the promotion of visual education any considerable group of educators, backed by sufficient capital to undertake the tremendous expense attending initial production. Occasionally small producers have made health education pictures of decided merit and value, but there was no avenue by which to secure general distribution among school and health authorities, and it

Fig. 1. Collecting tanks and gate house on Moon Island.

*The motion picture is a wonderful medium for the transmission of thought. It conveys impressions more rapidly than the voice by showing exact relationships and actions quickly, accurately, and vividly through the wonderful medium of the eye. Pictures which may require weeks to photograph will show the development of an egg to an adult animal in a fifteen minute reel. Through the "movie" the eye of the audience looks through the microscope, the telescope, or any other optical instrument. The animated diagram presents the hidden and internal operations of a mechanism. In scientific motion pictures the invisibly small is portrayed, the indiscernably distant is brought near, and the element of time is vanquished.*

was difficult for educators to find even those films which did exist.

Another difficulty in the development of educational pictures has been the restriction placed upon the showing of the films by state authorities or insurance organizations because of the fire hazard, and in some states the authorities have doubtless felt the pressure of the organized motion picture industry, whose interest it has been to have the strictest possible regulations in order that there might be few exhibition places outside the theaters themselves. The use of non-inflammable films, and the development of safe portable machines which show both lantern slides and films have made it possible for educators to urge new regulations, the adoption of which in many states has already made practicable the wide extra-theater use of films.

Not only has the fire hazard been removed, but other technical improvements promise much for visual education. There is sure to be further improvement in color photography and in securing better stereoscopic effects, and it is highly probable that

we may soon have some device which will make it possible to stop a picture on the screen. This would be of inestimable value to the health official and teacher, since they could use any part of the film as a lantern slide and, after the necessary explanations, set the picture in motion once more. The combined use of lantern slide and film on the same machine has already provided excellent opportunity for the lecture "movie."

### The Propaganda Film

There are three distinctly different kinds of instructional health motion pictures. One variety is what may be called the propaganda film. It is in part educational, but it is prepared for the general adult audience, and not for pupils. Its fundamental object is to arouse the enthusiasm of the observer for some worthy movement or organization, by depicting its activities and accomplishments. Several such films, for example, have been prepared by the Red Cross, and they have a distinct usefulness. Advertising films which show in an enlightening manner the process of manufacture of some food or sanitary product belong to the same class of pictures.

Commendable as these films are, they are not designed to be used in schools or where instruction alone is to be given. No matter how interesting the manufacturing process or how laudable the activities of the organization, the film is planned and produced in a different way than it would have been if its sole purpose had been education.

The second type of picture is the

Fig. 2. Boston sewage is discharged on the out-going tide.

Fig. 3. The "trickling" or rock filter.

drama which presents with its plot and human interest certain health information, leaving in the mind of the spectator correct ideas regarding the hygienic conduct of life without detracting from his interest in the drama itself. These pictures are for the theatrical and entertainment circuit, and have distinct possibilities for service. They are difficult to present because if they contain too much health instruction the action is slowed up and the picture fails "to go over" as an amusement feature. On the other hand, if the health instruction is entirely subordinated to the action of the drama, the point of the picture may be entirely lost. There is the further difficulty that unless such a picture is presented under the auspices of some organization or health authority which will vouch for it, the audience confuses it with the ordinary picture drama which makes small pretense of accuracy in presenting scientific details. In spite of these difficulties, a few successful pictures of this type have already been produced, and the genius who can present health truths through this medium in a way which people will enjoy,—just as Bunyan presented moral truths in "Pilgrim's Progress," and as Kennedy presented moral lessons in a different way in "The Servant in the House." will do a great service to society. The French report very good results from the use of such pictures in the campaign against tuberculosis.

### Systematically Educative

The third and most important type of health "movie" is the strictly educational film; and it is this type of picture which is being developed most rapidly. This variety of film takes on added importance because, from all appearances, both motion picture instruction and systematic health teaching are making their way into the school systems at this time. Interest in the educational phases of child health has been most keen since the war, and there are many indica-

tions that within the next decade a sound program of health education will be installed throughout the country. The activities of the child health demonstration which the National Child Health Council is undertaking in Mansfield, Ohio, the activities of the Committee of the American Public Health Association reporting on the School Health Program, the expansion of the activities of the Joint Committee of the American Medical Association and the National Educational Association on the subject of Health Problems in Education, the wide interest in the new dramatic devices for health education developed by the Child Health Organization, and the public utterances of leading administrators in the field of education all point to the rapid development of this field.

At the same time motion picture instruction in a variety of subjects is rapidly being introduced in the public schools. In Chicago, Detroit, New York, Newark, and several other large cities, as well as several smaller communities, visual education has already been made an integral part of the instruction. The most important development in this new field has been the organization of the Society for Visual Education, which includes educators from every state in the Union, and which has undertaken the production of series of school films in history, economics, civics, geography, nature study and physics, as well as in health and sanitation. Each series is being prepared under the direction of a special committee. The members of the Committee on Health and Sanitation are Dr. Victor C. Vaughan, chairman, Dr. Simon Flexner, Prof. F. M. Gregg, Dr. Ludwig Hektoen, Prof. E. O. Jordan, Dr. Wickliffe Rose, Dr. M. J. Rosenau, and the writer.

### Production Grows Apace

The Committee's production program has only just begun. The films already in general circulation include "Getting Acquainted with Bacteria," "Waste Disposal in Cities," and "Unhooking the Hookworm." This last film was prepared by the Rockefeller Foundation, and not by the Committee on Health and Sanitation. The Society for Visual Education is acting as a distributing agency in this instance. The future production program will be pushed forward as rapidly as possible and the new films to appear will deal with such subjects as: health habits; food values, and nutrition; the cleanliness of foods; posture; public health aspects of various

Fig. 5. The sand filter. After this process only 1 per cent of bacteria remains.

communicable diseases; sanitation of schools, factories, and cities; water supply; and waste disposal. All of these films will be short one or two reel subjects, and will be made primarily and solely for instructive purposes. The films which are now being prepared, although useful in higher education, are sufficiently non-technical in nature to be adaptable for pupils in the upper grades or for adult lay audiences.

The educational value of the films stands out above their entertainment possibilities and yet the interest in this novel way of presenting health information has been sufficient to make the films very popular. Moreover, health officials and educators who use these pictures need have no fear of exhibiting something which may have been seen already on the theater screen. The Society has adopted a definite policy of presenting these films only through educational or health authorities, and although a health officer may arrange for a theater showing, the theater itself cannot without his authority and cooperation secure the use of these pictures.

Some of the advantages offered by the motion picture as a method of presenting information are illustrated in the film "Waste Disposal in Cities," from which the accompanying illustrations are taken. This film outlines the direct disposal of sewage by discharge on the outgoing tide in Boston Harbor, and the more com-

Fig. 4. Each piece of rock becomes coated with bacteria.

Fig. 6. Bacteria under the microscope.

plicated sewage disposal process in the City of Brockton, where the sewage is forced from the pumping station to a purification plant, including trickling filters, septic tanks, and sand filters, after which the effluent is thrown into a small stream where a succession of bacteria, protozoa, other minute animals, and finally fish effect a rapid completion of the final stages of purification. Pictures taken through the microscope make clear the bacteriological processes which are involved, and the spectator sees both living and stained bacteria as clearly as he could when looking through the compound microscope. An animated diagram reviews every detail of the progress of the sewage through the purification plant, and presents in a minute a more vivid and complete impression than could be obtained by an individual who is not an engineer through a half hour's description even with photographs and diagrams. The process of stream purification and the appearance of various microscopic organisms which take part in it are presented as clearly as by a half day's trip along the stream itself.

### Shows Actual Conditions

The motion picture is a wonderful medium for the transmission of thought. It conveys impressions more rapidly than the voice by showing exact relationships and actions quickly, accurately, and vividly through the wonderful medium of the

Fig. 7. Trout live in this brook.

eye. Pictures which may require weeks to photograph will show the development of an egg to an adult animal in a fifteen minute reel. Through the "movie" the eye of the audience looks through the microscope, the telescope, or any other optical instrument. The animated diagram presents the hidden and internal operations of a mechanism. In scientific motion pictures the invisibly small is portrayed, the indiscernibly distant is brought near, and time is vanquished.

It is the purpose of the Committee on Health and Sanitation to utilize this new educational force to the best advantage in presenting health in-

Fig. 8. The purified stream.

formation to both children and adults in such a manner as to stimulate the desire for healthful living, and create a vital health conscience.

## Recent Hospital Rulings

THE Supreme Court of Georgia recently passed upon the question of granting a permit for the construction of a health resort and sanitarium. Sec. 729 of the Code of the City of Atlanta, which provides that "it shall be lawful for any person or persons, or corporation, to construct, erect, or build a house to be used as a private sanitarium, hospital, or boarding house, or other house of like character, wherein patients are kept, and medical surgical treatment is given or performed," except in the manner herein provided is within the police power delegated to the municipality whereby power is given to the mayor and general council "to control, regulate, and in its discretion prohibit the erection and maintenance of sanatoriums, boarding houses, and either similar places in residence portions of the city."

A building alleged to be used as "a tourist and health resort" is prima facie included in that class described as a "house to be used as a private sanitarium, hospital or boarding house, or other house of like character, wherein patients are kept and medical or surgical treatment is given," as employed in section 729 of the Code of the City of Atlanta.

J. Gilbert delivered the opinion of the court:

Under the police power the state has undoubted constitutional power to protect the public health and morals from improper use of private property.

Among the objections urged against the petition was that the property upon which it was proposed to erect a health resort was only 115 steps from the entrance to Piedmont Park; that Piedmont Park would become

an annex for crippled and deformed persons; that blood disease patients in petitioner's building would use and pollute the swimming pool in the park; that other hospitals would have to be allowed near the park; that children would be kept away from the park by parents on account of the nearness of invalids and convalescents in the building of petitioner; and that the health resort would commercialize the park. It would seem that public parks of a city are intended for the free use of sick persons, cripples, invalids, and convalescents, as well as persons enjoying perfect health, children and their nurses. So far as we are aware, it has never been suggested that any one or more classes can be arbitrarily prohibited the use of a public park directly or indirectly, or that their presence is unwelcome.

We think it is obvious that a "tourist and health resort," as described in the petition, not only is not per se harmful to public health and morals, but, when properly located and conducted, is legitimate, beneficial, and humanitarian. Notwithstanding the fact that the business is not per se injurious to public health and morals, it belongs to that class included within the control of the police power of the state. It would be an arbitrary and illegal exercise of power to decline the permit, unless it was shown that the building was injurious to health and morals."—*Blackman Health Resort v. Atlanta*, 107 S. E. 525.

Facts, like rights, are only relative, never absolute, and only take on meaning when arranged with reference to other facts.—Todd.

# Medical Training for Social Workers

By FLORENCE MEREDITH, M.D., LECTURER IN MEDICINE, SMITH COLLEGE TRAINING SCHOOL FOR SOCIAL WORK, AND NEW YORK SCHOOL OF SOCIAL WORK; PROFESSOR OF HYGIENE, WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, PHILADELPHIA, PA.

SINCE the year 1900 doctors in hospitals have come in contact occasionally with individuals known as "medical social workers." To many of the doctors this individual was understood to be a most valuable part of the hospital work wherever she was found. To others she was a person undeniably of large sympathies, but often of small preparation for her chosen work. The best social workers of the past have been those endowed naturally with an understanding of human nature which has developed in them an ability to step into the affairs of others and straighten them out. Some had in addition special training in theoretical sociology and some in nursing. The outstanding feature of the early social worker, however, was her natural qualification for gathering together the scattered ends of individual, domestic, and community relationships, and joining them in a way that should result in the welfare of all concerned. In fact, for a time the word welfare was used in connection with her work. The term "social adjustment" is now in better repute.

## Develop Definite Technic

The outstanding lack in the social worker of the past was that of a definite technic developed through organized study of her profession. This was not always a lack, for certain individuals had the ability to develop a marvelous technic from their own experience.

Rather recently there have been schools for training in the profession of social work, as there should be for all professional training of course—schools that devote some time to theoretical training, and more time to supervised practice training.

This sort of training, while it is essential for all social work, is particularly so in preparation for medical social work. In the year 1918 Smith College opened a school to train social workers to meet an emergency produced by the war for psychiatric social workers. The following year other courses were added in medical social work and community service. It is probable that the curriculum will soon be further extended. The New York School has also been giving training for medical

social workers, the present plan having been inaugurated this fall.

Those who have planned the course in medicine for social workers have had in mind the necessity for considerable knowledge of both medical practice and the technic of social work, neither perhaps being fundamental to the other, but each being carried on more effectively by the side of the other. Hence the preliminary requirements are neither previous training in social work, nor in nursing or medical sciences, but a broad education equivalent to that essential for the A.B. degree.

As to the teaching of medicine, we endeavor to give a bird's eye view of the whole subject, beginning with a general study of anatomy, gross and microscopic, and physiology. This part of the work is as brief as is consistent with an intelligent understanding of later subjects, and for lack of time cannot include laboratory work. Those students who are so fortunate as to have taken biology and chemistry, possibly also physiology, in college, have an advantage in the early part of the work, but are usually not given credits that will exempt them from any part of the course, because the point of view will be somewhat different

in courses particularly designed to enable the social worker to deal with medico-social cases, rather than to have a theoretical and laboratory knowledge of these sciences.

As rapidly as possible progress is made toward habits of living that make for health and of a study of pathological processes as they appear in the patient.

By this training of social workers in medicine, several things are expected, which do not include of course the making of accurate diagnoses, least of all any suggestion as to definite medical treatment. First of all, it is hoped that the student will be able to get a grasp of the principles of right living, so that she may spread them abroad wherever she goes. To be sure, these rules differ with different individuals, and would thus better be prescribed individually wherever possible. But since it is manifestly impossible to do this for each of our hundred millions, there must be a more extensive application of the general principles of hygiene that are a good basis for health making. Much has been said about these principles—the need of fresh air, and a balance between work and rest, sufficient sleep and recreation, proper food and clothing, and all the

Smith has introduced into the technical training for social work such generalizations in medicine as afford a good basis for health building.

others. But they have usually not been said by individuals to individuals—by informed individuals to individuals who are running counter to these principles.

### Background of Symptoms

Bearing in mind the necessity for physical examinations even of those who are well, for the purpose of keeping so, social workers may often make simple suggestions with such force that they turn the balance from a state of "ailing" to a state of health. They should be able to determine, however, when such suggestions would be unwise, and when the individual must be brought into closer touch with medical science.

For this purpose social workers must have a discriminating knowledge in regard to the signs and symptoms of disease. They should know for example, when an individual shows such a symptom as cyanosis, and should know that no advice from a layman is adequate in such a case, but that the individual should be thoroughly examined for its cause and treatment. This being able to discriminate with some degree of accuracy between the sick and the well is one of the things we hope for, not that a diagnosis of the cause of the cyanosis be made, but that the various possibilities in such a case be recognized and the case be dealt with suitably by getting him to a doctor.

One of the questions in the recent examination at the end of the summer course at Smith, was "State as many causes of headache as you can." A headache is often not simply a headache, and we expect the student to realize this. That they do so is testified to by the fact that one student enumerated twenty-two fundamental causes of headache.

By recognizing the possibilities in symptoms there is opportunity for excellent medical social work entirely apart from a hospital social work department, individuals who have never been to a hospital or a doctor being directed thereto by a social worker with medical training. For this reason we hope ultimately to have all our students so trained, whether they intend to specialize in hospital social work or not, so that they may first, while dealing with the well, see that health education is given to conserve health. The privilege of doing this is not often given to doctors, except through public speeches and printed articles. Doctors do not see the well, as a rule. It is a well known fact that not more than 5 per cent of the

The preliminary requirements of the students are neither previous training in social work nor in nursing or the medical sciences, but broad educational preparation and the necessary personal qualities.

population is at all regularly in contact with medical science. The other 95 per cent includes many who are actually ill, and many who would greatly profit by a physical examination although able to be about and working. The physical examination for each and every individual will more quickly become a reality after medically trained social workers are in the field in larger numbers. In addition they may, as already suggested, help to sort out the sick from the well, giving health education to the well, and getting the sick where they belong. The average layman is not only unfamiliar with the common signs of ill health, but often holds mistaken notions about them. If the social worker, by using judgment in this field, wins the confidence of the public, she will prove the most important connecting link between medical science and the public that needs it.

In the second place, we expect our students to learn not only signs that indicate disease, but to understand the relative seriousness of certain diseases, so that they will more than ever exert every effort to see that treatment is carried out, and that those who need continued care are kept in touch with that care. Without a knowledge of the possibilities in a case, for example, of endocarditis in a child, even though the doctor is explicit in his directions to the mother, there is a large chance that the case will be permitted to

live in such a way as to make lasting bad results inevitable. Often it is the social worker who must supply to the family the feeling of the importance of following each detail of treatment, and moreover to adjust matters so that this may be done—both sometimes stupendous tasks.

### Personal Adjustment Counts

Furthermore we hope that the students will get an adequate grasp of the way in which social maladjustments lead to disease, and conversely of the way in which disease leads to social maladjustment. In one case she will find the former state of affairs, in another, the latter. More often, however, she will find a vicious circle where disease and maladjustment are coincidentally reinforcing each other. It is breaking into these vicious circles that the social worker can accomplish the most brilliant results.

The doctor in private practice must as a rule do this for himself, in so far as he is able. But in dispensary work it is impossible, on account of the volume of the work if for no other reason. Even supposing the doctor to be quite aware of the ramifications of a case into other fields than medicine, he is as a rule tied to his medical work, and has neither the time nor the ability, although sometimes he has the inclination, to leave it for such adjustments. Those of the medical profession who have felt this need of an extension of medical

No credits on the basis of previous work are given to exempt any of the students from any part of the prescribed work, as it is felt that a point of view is developed which is important in carrying out effectual social work in medicine.

work into the individual and family social condition (and who has not, who has worked in a clinic?) have often been tempted to use their own possibly good natural ability to solve these problems. But, after all, it is not that for which they are particular trained, and it is not an economical arrangement for the person trained in one field to spend his time in another. The person trained in medicine should be devoting his time to medical work as such, and the extension of medical work into other fields should be cared for by others, providing others can be found with sufficient knowledge of both the medical and social field.

We therefore expect our students to understand what doctors are trying to do medically, and in their own way to supplement work that otherwise will often be futile.

Finally, we expect the students to be in sympathy with all the great movements for public health—those conducted both by the various divisions of the government, and by private organizations. The individual may often be helped more through such large work than through personal work. Medical social workers may elect to ally themselves with work of this scope. At all events, if they continue to work with individuals it will be necessary that they know the forces working for health upon which they can call for assistance. There is often in the community just such a rest home as the

parturient mother needs, for example, but the doctor does not know it, nor the patient; hence it may not be utilized in the most urgent cases. At the other end of the problem we have the institution doing admirable work but not adequately supported because the public does not know of its needs.

To sum up, then, the aim in training medical social workers is, first, to produce social workers. They should be, above all things, social workers, knowing all there is to be known about social work. Secondly, it is to add to this knowledge of their own profession sufficient knowledge of medicine that they may correlate medicine and social work so that each may act more fully for the benefit of mankind.

### Occupational Therapy Used In 37 Hospitals

Occupational therapy is used in 37 hospitals for nervous and mental patients in the United States according to answers received from a questionnaire sent to all state and private hospitals for nervous and mental diseases by the committee on occupational therapy of the American Medico-Psychological Association. Dr. H. J. Gahagan, former superintendent of the Illinois State Hospital, was chairman of the committee.

Of the fifty-two institutions which replied, a small percentage of the total number, thirty-seven replied in the affirmative, while fifteen stated

that occupational therapy was not used. The average number of hours the patients are employed was stated to be four, maximum six, with a minimum of two hours daily.

### "New Eyes" Are Given to 200 New York Children

Out of 100,000 pupils in the New York public schools who fail to be promoted each year, 50,000 have defective eyesight, according to a report from the Eye Sight Conservation Council of America, New York City.

The Junior Red Cross has established a \$5,000 fund to aid parents in buying glasses for their children. Already two hundred children have been given "new eyes," according to a report issued by a local chapter of the Red Cross.

The Council recommends that every child who does not see well and every cross-eyed child be examined at the age of three or four years. That the eyes of every child should be tested before he enters school and every year thereafter is also a recommendation of the Council.

### Detroit School Children Have I. Q's Taken

A comprehensive program of psychological examinations has been developed in the public schools of Detroit under the direction of Prof. Chas. S. Berry, of the University of Michigan. Various group tests of general intelligence have been applied to all children in the city who are three years or more retarded in school work, and to all first grade children. The results of the work show that when pupils are classified according to general intelligence, all groups of children progress through the schools more rapidly. The need for differentiation in the course of study for the different types of ability is also shown.

### N. C. Child Workers to Have Physical Tests

The North Carolina State Child Welfare Commission, which has power to prescribe rules and regulations for the issuance of employment certificates, has ruled that on and after March 1, 1922, a physical examination by a health officer or practicing physician, according to forms approved by the Commission, shall be required of all children under sixteen years of age who make application for employment.

## The Ill-Used Organ, the Skin

INCIDENTAL to his studies on the therapeutic action of the sun, Rollier, of heliotherapy fame, recently made a strong plea for that much ill-used organ, the skin. We are prone to regard with a complacent superiority the way in which less enlightened races maltreat their bodies, but we ourselves would do well to imitate more closely certain less cultivated races with regard to the treatment of the skin.

The paramount importance of this organ cannot fail to be realized when we consider the complexity of its functions. In the first place it is an admirable protection against pathogenic organisms. It is the seat of cutaneous sensation, and an excretory organ of importance second only to the kidney. It is very closely concerned in the delicate mechanism regulating the temperature of the body; and, finally, as a vascular layer it plays an important part in the nutrition of underlying tissues.

By overburdening the body with clothes every one of these functions is interfered with to a greater or less extent. Rollier makes the frequent observation that the resistance of a patient against disease is closely proportional to his degree of pigmentation, and pigmentation does not take place under clothes.

Cutaneous sensation is much more delicate in the uncovered regions of the body, and it is equally obvious that heavy clothes, by preventing free evaporation, interfere with the excretory functions of the skin. The contrast between the tolerance to wide ranges of temperature shown by the face and hands and the extreme sensitiveness of the rest of the body gives some idea of the extent to which disuse atrophy of the heat regulating mechanism has taken place.

### The Skin and Its Reactions

It is, however, our chief concern at this time to consider the functions of the skin as a surface organ: (1) It is the first line of the bodily defense, receiving all direct injuries from without. (2) It is the first tissue to be chilled or warmed by changes in external temperature, thus being the outpost for heat regulation. (3) Being the first organ to come in contact with other bodies, it thus becomes the intelligence department of the central nervous system. (4) It is the only tissue visible to others and is therefore available for attracting or repelling them, or for

evading them by disguise. Although the skin is intimately associated with certain inner organs, it is chiefly a receptive organ and the relationship is primarily from without inwards.

It is evident that the well being of the worker will be greatly affected by any condition that interferes with the integrity of the skin. Numerous recent studies have to do with industrial dermatoses, the cause of many of these conditions being traceable to personal habits, subject to intelligent reform, or with environmental conditions, open to improvement through industrial hygiene.

The whole subject of dermatology is becoming more closely bound up with scientific medicine owing to the difficulty of separating the problems of skin idiosyncrasies from constitutional conditions, but on the whole, according to Dr. Arthur Whitfield, in the *Lancet*, the success of local measures compared to internal treatment is very striking. The expert in skin diseases is so often confronted with diseases of purely local origin, such as scabies, ringworm, etc., treated as some obscure constitutional condition that he is apt to become prejudiced against internal factors as a potent cause.

### External Irritants

It is, of course, of the greatest importance to identify and remove the external causes of chronic skin irritations, especially in view of the readiness with which the primary lesion from whatever cause can become the location of later and more serious infections. Eczematous affections due to constant exposure to certain dusts, chemicals, or oils find their remedy in specific correctives directed against the existing condition. For instance, the preventive measures recommended by William J. McConnell against the industrial dermatoses among printers was, first and foremost, soap and water cleansing, afterward rubbing the hands and exposed parts with lanolin to supply a coating more or less impervious to the irritants.

Dr. Robert T. Legge, in the *California Medical Journal*, recently enumerated the occupational diseases of the skin and hands in California industry. Along with special correctives for specific irritants he emphasizes personal hygiene on the part of the workers, and the efficacy of soap and water cleansing. In several states which gave attention to spe-

cial measures of health legislation, increased emphasis was placed upon the provision of adequate washing facilities for the workers, with a plentiful supply of hot and cold water, and pure soap.

### Special Susceptibilities

The choice of soaps is particularly important. Certain skins which are deficient in natural oils require careful handling and the use of well milled, bland soaps. Our knowledge of the defensive reactions set up in the skin is not very complete, but it is assured that certain antiseptic preparations act as particular irritants to some skins and that this type of skin reaction to some particular kind of substance is more common than is generally recognized. The same remark would apply to toilet preparations and probably to ointments in common use. Inquiry will often show that outbreaks in skin disorders follow shortly after the application of some "new material" to the skin. Skin hygiene involves intelligent attention to individual susceptibilities, preventive measures directed especially to industrial irritants, the prevention of contact contamination as far as is reasonably possible, and especially to thorough and repeated soap and water cleansing of the skin, particularly of the hands.

## The Pitiful Ballad of a Pop-Bottle

### *Sanitary Vers Libre*

I am a pop-bottle.  
The sand of which I am made was purified  
by fire  
And blown into a mold.  
When I reached the bottling plant  
With several thousand of my fellows,  
I was washed and steamed  
And filled with a beautiful red fluid  
Made of water, syrup, and wind.  
I was taken to a shop  
Where little children came for  
All-day suckers and other junk.  
My beautiful red contents were poured  
Into a glass which had just been used  
By a kid with  
A runny nose, fever, and a cough.  
The glass had previously been  
Sloshed around by the hand of the proprietor  
In a bucket of water which was changed  
At least once daily.  
The proprietor's fingers were in mourning.  
It was not long before  
The little girls parents were also:  
For she died of influenza.  
Every time I went back to the bottling plant  
I was cleaned and sterilized.  
But this was not always easy.  
Once between trips  
I took a sample of urine to a doctor's office:  
Once I was used as a nursing bottle:  
Once I carried gasoline to a car  
Which had given up trying  
To run on its reputation, and  
For a while I was used  
As a container for home-brew  
Concocted in a dirty kitchen.  
By a man who should have known better.  
The Health Officer worried a good deal  
About the purity of the water, syrup, and  
wind  
Which went into me at the factory, but  
If he could have seen the way  
I was used between times,  
He would have had a convulsion.

## Health Emphasis Has Given Direction to Health Trends

ACCORDING to the records pooled and published by thirty-seven leading American life insurance companies, 1921 was the healthiest year in the history of the United States and Canada. The six chief causes of death, in the order of their importance, are: Organic diseases of the heart; tuberculosis (all forms); Bright's disease; pneumonia (all forms); cerebral hemorrhage; and automobile accidents. Twenty-eight per cent of the deaths during the year are charged to the maladies of the more advanced years of life and, as they are caused by diseases which, because of "our present conditions of life are pretty sure to continue at high ratios among the causes of death," they are not to be made the special object of corrective effort by the insurance companies.

We are not inclined to concede the futility of effort to lower the death rates in the 28 per cent of deaths resulting from the degenerative diseases; but insurance companies—with whom improved health conditions register an immediate and tangible financial gain—are usually unwilling to gamble on a possible change in personal habits in cases involving extra risk and, therefore, focus their efforts in the direction of health betterment in the more hopeful 72 per cent who are taken off by tuberculosis, pneumonia, etc. Respiratory conditions are difficult, but not hopeless to combat, and it is considered that with a

better understanding of the operating causes of the increased number of suicides these fatalities will be open to remedy. The mounting ratios of automobile deaths threaten a rating up in certain forms of protection,—a bad commentary on a condition that could well be socially controlled.

In the industrial field, particularly, insurance rates may be taken as a guide to the hygienic conditions surrounding different occupations. While the industrial physician is perhaps entitled to the credit of recognizing the gain in community health which would result from the hygienic reorganization of certain industries, the wide application of hygienic principles was made possible by the insurance companies on the basis of statistical knowledge of under-average lives. The service of workmen's compensation, usually emphasized from the angle of its distribution of the burdens of unanticipated contingencies, is really greatest in the resulting hygienic and safety work made urgent through the onus of compensation upon industry.

However much health betterment projects on the part of the employer are impugned on grounds of being activated by self-interest, economic considerations have served to make stable and universal the health protection of workmen. Individual inertia on the part of the public, and a current sense of a certain inevitableness of disease, may yet give way to self-instituted and self-maintained health programs in industry but, so far, except in isolated instances, self-help in health matters has required an outside stimulus. Progress is being made, however, and we still look to see the whole people translate into rules of behavior the laws of health which have been demonstrated as favorable to fuller and longer living.

## Child Labor Conditions a National Problem

IN AN open letter urging the nation-wide observance of Child Labor Day on January 29, Mr. Herbert Hoover makes the statement that every child in the country who labors to the prejudice of health and education is a liability to the country. It is safe to say that wage-earning on the part of children in every case makes inroads on both health and educational development. Lengthening the period of youth tends to prolong the period of productivity. "The play time of youth is the 'prentice time for educating aptitudes in after-life." The child is so much in the grip of his environment and his increase of efficiency is so greatly dependent upon constant encouragement and stimulus that the fatiguing routine of unvarying tasks must involve for him a distinct menace.

Child labor lowers the child as a social asset of the future. "In times past at certain levels the child used to be regarded as a savings bank from which the parents could draw early; if children are nowadays regarded as investments, it is only on the understanding that they cannot yield a rapid return. Consciously or subconsciously the economic consideration lingers, but it has not the force that misery lent it in the worst days of unregulated industrialism. A new consideration has arisen. There is a heightened appreciation of the value of human life; the child is more precious."

Child labor as a national institution is not necessary; it is not training—notwithstanding certain statements recently made to the contrary; it is not advisable, nor held so except as opinion is influenced by self-interest. The institution of Child Labor Day is significant as indicating a change of sentiment on the part of the people from the exploitation of child life to its scientific nurture. Children under certain conditions grow old prematurely, or are "born old." It becomes a social duty to extend youth into the period of age rather than to deprive the child of time to grow up.

---

### Controversy Obscures Facts in Compensation Decisions

THE problem of ascertaining and proving the existence of facts before a court of law lies at the basis of many of the compensation decisions. The province of the court is to determine the law on a given point, but how about the facts? The administrative or compensation boards have been appointed to meet this situation, to ascertain and determine upon the facts. They are given facilities and powers to investigate and hear controversies,—to make independent inquiries if necessary. But is their decision final? The courts of course have no facilities for getting information and material. They must decide on a case as it is presented to them unless a thing can be shown to be of general knowledge and one of which they can take judicial notice. How far, then, will they go in adjudicating with regard to the findings of the commissions? The practices of course vary in different states, but it is generally conceded that the courts will interfere to control abuse.

But what is abuse? Court decisions in Illinois seem less liberal in one case, while those of Michigan seem more liberal in another. The whole thing is in a state of flux. The discouraging feature is perhaps brought out most clearly in the case of the St. Louis Smelting & Refining Company v. Industrial Commission, 131 N. E. 617,

reported in this issue of THE NATION'S HEALTH. If, as was brought out in the testimony, the employee in question actually had the blue gum line and other characteristics of lead poisoning, their existence should be shown with sufficient clearness to be incontrovertible. Facts of this nature can and should be definitely ascertained, and the fundamental issue would not then be obscured by moot questions of whether plumbism may be the cause of erysipelas, or sciatica an inevitable result of carious teeth, but concurrent conditions would take their position of relative importance, not as the controlling factors, which in this case as in others is the burden of proving the actual existence or non-existence of a disease or condition traceable directly to or "arising in or out of the employment."

---

### Regulation of Bottling Plants—An Important Health Problem

THE Alabama State Board of Health in its recently issued bulletin promulgating the sanitary regulations governing the operation of bottling plants has adopted the policy of appending to each section a statement couched in simple language explaining and interpreting its *raison d'être*. An excellent plan this, since it clarifies the intent and purpose of the regulations both to those who must obey and those who will enforce them. It also makes apparent the "sweet reasonableness" of the rules laid down and secures a much desired cooperation.

The great increase in the number of soda water fountains and the use of charged beverages in general, makes it very important that the bottling industry be carefully supervised, since the vending of impure drinks constitutes a serious menace to the public health. The passage of the Eighteenth Amendment seems to have imbued the general public with a desire to drink something out of a bottle anyway, probably on account of the memories of the times when fluids coming in such containers at least created a temporary sense of beatitude and joy, but the soft-drinking public has yet to acquire that sense of fine discrimination which once was the earmark of the alcoholic devotee. Until such time as the people at large have learned to demand purity in their soft beverages they must be protected to the nth power.

Not only does the application of these regulations act to protect the consumer by insuring the purity of the raw products and their aseptic preparation for vending, the manufacturer is also guarded in a way against the financial losses which follow the use of inferior materials carelessly mixed and bottled. Quite as important is the protection against demands for cash settle-

ment and expensive legal processes which may be caused by the sale of a single bottle of an impure or dirty beverage. It is therefore imperative that bottling plants shall use a pure water supply, that the syrups used shall be free from gross foreign particles and other contamination and that the bottles themselves shall be thoroughly cleaned and disinfected before filling.

When a public water supply is used, it is as a rule safe, thanks to the very general advances which have been made along this line, but frequently the purification processes to which it has been subjected render it unsuitable for carbonation, hence many plants depend upon privately owned wells. The danger of these, if not subjected to regular examination and close supervision, is apparent.

The problems connected with the syrups and coloring matters are largely the prevention of spoilage by molds and the removal of sediment and other foreign matter. Mechanical cleanliness of all containers and piping used in handling them is an essential, as is also their compliance with the Food and Drugs Act.

In spite of all these precautions and the exercise of the greatest care in the preparation of carbonated beverages, the final product cannot be cleaner than the bottle in which it is dispensed. The cleaning and sterilization of bottles is therefore an important and painstaking process. The bottles must be soaked in a solution of caustic soda, soda ash, baking soda or similar chemicals to soften and remove gross filth and labels. The solution should have an alkaline content equal to at least 3 per cent sodium hydroxid and a temperature which never falls below 120 degrees F. Following the soaking process, the bottles should be brushed inside and out to detach any remaining dirt and then thoroughly rinsed until clean. They then should be sterilized by steam and filled, care being taken that the caps are clean.

---

### Blindness in Children—Its Causes and Prevention

**F**FIFTY per cent of the blindness of infancy is due to the preventable disease, ophthalmia neonatorum.

"Fifty per cent of the blindness of school children is due to parental venereal disease."

"The true figures for 'all ages' are seen to be, blindness from gonorrhoeal disease 2.5 per cent, from syphilis 9 per cent."

These quotations from the discussion on the cause and prevention of blindness before the Section of Ophthalmology at the last meeting of the British Medical Association by Mr. N. Bishop Harman drive home the fact that the children, as

well as the women, pay. Mr. Harman's figures are derived from three sources, a home for blind infants, the schools for the blind and partly blind of the London Education Committee, and private case books, and relate to a total of 4,288 persons.

In the National Institute for the Blind, recently opened, sixty-three blind babies were examined and of these 31, or 49.2 per cent, were blinded by ophthalmia neonatorum.

In a group of 699 blind or partly blind school children whose blindness was due to injury or destruction of the cornea subsequent to surface inflammations, 367, or 52.5 per cent, owed their condition to ophthalmia neonatorum. In this same group, out of 90 cases of purulent conjunctivitis of later years, were two cases demonstrating forcibly the danger to other members of the community of babies suffering from gonorrhoeal ophthalmia. To quote Mr. Harman, "One is a girl whose motherliness was exercised towards an affected baby; she caught the disease; the cornea ulcerated and she is blind for life; the baby died. The other is a member of a family of three girls; the youngest, a baby, had the disease; the whole family contracted it, besides suffering from vaginitis; the eyes of one of the children were damaged sufficiently to necessitate her being educated in a blind school."

Of 413 children of school age, 284 of whom were blind and 129 partially sighted, suffering from inflammation of the anterior half of the eye, 369, or 89.3 per cent, were blinded by syphilis. This percentage does not take into account twenty-nine additional cases probably also caused by syphilis. If these were included, the percentage would be 96.3 instead of 89.3 per cent.

There were 349 cases of disseminated choroiditis, in which all the evidence went to prove that this condition in children is overwhelmingly syphilitic in origin. To be sure, this condition is not absolutely pathognomonic of syphilis, but most of these cases are caused by that disease; thus out of a group of which 294 were blind and fifty-five partially sighted, 210, or 60.1 per cent, were the subjects of congenital syphilis. To this infection is also attributed twenty-eight cases of congenital defects out of a group of 408. Recapitulating; out of 1,855 cases of school blindness, 19.89 per cent were due to gonorrhoea and 33.31 per cent to syphilis, a total of 53.20 per cent caused by venereal disease.

In another group of 925 persons of all ages, mostly adults of all classes, 2.48 per cent were due to gonorrhoea and 9.19 per cent to syphilis.

It will be noted that the incidence of blindness from these diseases drops progressively from infancy onward. This is probably due to the fact that a considerable number will have died before

reaching the next age group and also because other causes of blindness have begun to show themselves as age progresses.

The pitiful part of this wholesale blinding of little children is the fact that it is wholly preventable and therefore unnecessary. Furthermore, these results are brought about by no act of the children themselves.

The care and treatment of expectant mothers, the immediate treatment of the eyes of the newborn with silver salts, the prompt hospitalization and active treatment of all babies showing inflammatory conditions of the eyes, will go a long way towards preventing gonorrhoeal ophthalmia. Midwives and obstetricians should be required under heavy penalty immediately to report any inflammation of the eyes, no matter how apparently trivial it may appear and every health department should have at its disposal a sufficient number of ophthalmologists to diagnose speedily and rapidly treat any such cases. Equally necessary is a well qualified ophthalmologic surgeon on the active staff of every lying-in hospital.

The great desideratum, however, is the repression of the venereal diseases themselves. This means education, education, and still more education. Perhaps the great publicity which the anti-venereal disease campaign received during the war is bearing fruit already, but it seems a trifle early to expect marked results so far as the ocular infections are concerned. It may be pointed out, however, that in 1913, 24.17 per cent of blindness in a group of English school children was caused by gonorrhoea, whereas in 1920 the percentage was 19.79, a fall of 4.38 per cent in seven years. This looks encouraging, but on the other hand, in this same group in 1913 the percentage of syphilitic inflammations was 29.70, while in 1920 it was 31.43, a rise of 1.73 per cent. This rise is probably more apparent than real and is due to the mathematical rearrangement due to the fall in the ophthalmia neonatorum rate.

The fact remains, however—the horrible, unescapable fact—that it is the little children who pay and the prevention and eradication of venereal diseases will go far toward reducing blindness among them.

---

### The Relation of Mucus and Saliva to Oral Hygiene

IT IS a current phrase that "the clean tooth never decays," and within certain limits this is true. We have, however, assumed—perhaps unconsciously—that the only way a tooth can be maintained in a cleanly condition is by brushing it. While this is also in a way true, in view of the dietary which we modernists use, there is no

doubt that Nature has a tooth cleaning brigade of her own which if given half a chance functions fairly well. In all probability this process goes on continuously in all mouths more or less efficiently and tooth brushing, and the various other processes of accomplishing oral hygiene artificially, merely aid and supplement this natural function.

When the dietary consists of semifluid mush, it simply receives a few perfunctory squeezes from the teeth and a few general directions from the dorsum of the tongue and the hard palate and is on its way. Pre-masticated pabula like porridge, custards, and similar foods are not chewed and hence do little in the mouth except to mingle with the mucus stagnated on the teeth. This compound, unless removed artificially, becomes infiltrated with the salivary salts, thus forming tartar, or it undergoes lactic acid fermentation with decalcification of enamel and subsequent dental caries. If, on the other hand, the food contains fibrous, tooth-resisting substances, there is a stimulation of the masticatory processes and the teeth are scoured by the muscles of the cheeks, tongue and lips which, with the grinding movements of the lower jaw, press the fibrous portion of the food against the teeth and mechanically clean them. Thus it is found that if only one side of the dental arch is used, the other accumulates mucus, tartar, and food detritus and is quite apt to become carious. The tearing and macerating process which is accomplished by complete mastication renders the food semifluid, hence the lubrication of the bolus which was formerly believed to be the function of the mucus becomes superfluous and the alkalis of the saliva largely prevent the precipitation of caseous mucin and the formation of mucus plaques.

As for the ptyalin itself, it is now believed that its function is not the digestion of cooked starch in the stomach into achrodextrine and maltose as was formerly taught by the older physiologists. Modern students now hold that its function is rather that of an important adjuvant to oral hygiene by the digestion of carbohydrates left in the mouth and in making the mucus alkaline. Further, the salivary corpuscles may act as oral scavengers. The acid reaction of the saliva during the resting period may be important because of the fact that it favors the action of the liquefying bacteria and its salts seem to have a restorative value by rehardening the superficial enamel.

The diet plays another very important rôle in oral hygiene through its accessory factors. Perhaps as striking an example of this as may be quoted, is the dental change which is seen in scurvy, a typical deficiency disease, and many

observers believe that devitaminized food exercises a very deleterious effect on the dental mechanism in many unclassified conditions. Conversely, it has been stated very recently that the excellent teeth of the American Indians who have not adopted the diet of the white man may be accounted for by the high vitamine content of the many plants and shrubs which they chew or use as infusions.

So long as our dietary contains so much pap and dead accessory factors, we must place our great reliance on the tooth brush, but this useful hygienic instrument may be greatly assisted by the exercise of the teeth on more resistant food-stuffs.

---

### An Appraisal of the Value of Athletic Sports for Girls

IT IS remarkable that in an age in which so much attention is being given to the conservation and upbuilding of health that there should still be left any remnant of Victorian superstitions regarding the ill effects of exercise upon girls—exercises which we encourage in their brothers. Yet there are many mothers who believe that their daughters are constructed of a different protoplasm from their sons, women who believe in the deleterious results of fresh air upon the growing girl, and regard a crop of freckles as a catastrophe. Such mothers forbid their daughters to engage in games and limit their exercise to the syncopated toddle. There is no quarrel with the rhythmic exercises of the ball room, which as conducted nowadays certainly bring into play the entire musculature, but they can never take the place of games in the open air. To be sure, the average girl today takes much more exercise than did the debutante of a decade ago, but even at that she does not engage in games to the extent of the average boy.

There is something in games besides mental diversion and muscular development. Drills induce concentration, obedience, and action in co-ordination with others. They are also of value in the correction of postural defects, but they lack the inspiration of the competition which is an integral part of such sports as tennis, hockey, and la crosse, which produce a mental alertness, a sense of fair play and a realization of community of interest not to be cultivated in any other way. Walking, cycling, swimming, snowshoeing, and skating are admirable forms of sport, but unless they can be conducted in competitive matches, they lose much of their health value. A cross-country race is an exhilaration; a cross-country walk, just to be walking, is a deadly bore. The one is a joy which is reflected throughout the

whole body; the other simply results in fatigue.

Girls may engage in almost any sport with great profit. It is doubtful if they should box, on account of the harmful effects which may result from a blow on the breast, and they are not heavily enough built to engage in real football, but with these exceptions there are practically no games which they may not play with great profit.

It used to be thought, and the superstition still is widespread, that menstruating girls cannot bathe. Many still believe that they cannot engage in games during this period. It must be admitted that at such times their coordination is below par—this is particularly noticeable in women golfers—but there is no need for them to abstain either from baths or athletic pursuits at this time. Several physical directors of schools for girls have observed that girls who go in for games have fewer menstrual troubles than those who stay on the sidelines.

To be sure, certain girls, just as certain boys, should not indulge in violent or prolonged exercises. Enlarged thyroids, bad hearts, and the like all preclude; but, taken by and large, the girl who plays games has more moral, mental and physical endurance than those who do not. Neither boys nor girls should be subjected to severe physical strains, but there is no reason why in games of speed and skill, girls should not be the equal of boys and, making allowance for difference in stature, they should be as strong as their brothers. For both there is the danger of overfatigue, overtraining, and overattention to games at the expense of studies, but these are easily controlled and there is no more reason why athletics should coarsen their social fiber than that equitation should make them "horsey."

---

### The Value of Toxinantitoxin in Preventing Diphtheria

IT IS unfortunate that in spite of the specific action of diphtheria antitoxin on diphtheria toxin, the mortality from diphtheria is appallingly high. Whether the fault lies with the physician who neglects to detect the disease in its early stage or with the parents who neglect to call a physician early in the disease, the fact remains that something should be done in order to lessen the mortality from diphtheria.

The work done by Park and Zingher on toxinantitoxin holds out a ray of hope that in time diphtheria will not only be cured but also prevented. Toxinantitoxin seems to have a distinct value in preventing diphtheria. Whether or not the sweeping claims made by the New York Board of Health will be substantiated, there is an

efficacy in toxinantitoxin which deserves consideration on the part of various boards of health and of practising physicians. It is to be regretted that so far nearly all the information we possess on toxinantitoxin has been furnished by the New York Board of Health. While no one can doubt the sincerity, honesty, and accuracy of the persons connected with the research department of the New York Board of Health, one likes to see work of this nature corroborated by persons aside from the originators and promulgators of a certain idea.

Outside of an unfortunate accident that took place in Dallas, Texas, due most likely to some mistake in the preparation of the toxinantitoxin used, no evidence has come forward that toxinantitoxin has any deleterious effect on the patient. There is, therefore, good reason to employ the preparation in public schools and in infant asylums in order to give the method a thorough trial. We must not make the mistake that some physicians made at the time antitoxin was introduced by Behring. As is well known, some of the very best medical men in the world have opposed antitoxin and thereby permitted the death of many children. As long as the preparation seems to be harmless and to a marked degree effective, it should be employed by health authorities.

Of course no preparation of the type of toxinantitoxin should be commercialized without the proper supervision. There should be a unit of strength for the preparation just as there is a standard for diphtheria antitoxin, tetanus antitoxin, and various other sera. The average physician does not want to use any preparation that may have the least toxicity in it unless it has been fully tested by health authorities. Meanwhile, one must not be misled by the literature put out by certain irresponsible persons condemning toxinantitoxin.

---

### Sheffield, England, Employs New Method of Sewage Treatment

**R**UMORS have been current for a year or more in regard to interesting developments in the art of sewage treatment at the city of Sheffield and definite data are at last at hand in a paper presented by Messrs. John Haworth and F. W. Hodgkinson before the Forty-eighth Annual General Meeting of the Institution of Municipal and County Engineers at London, June 15-18, 1921. The fundamental principle in the work of these investigators was the assumption that the air supply in the ordinary process of activated sludge treatment serves the double purpose of agitation and aëration, and that the aëration need in itself is relatively small. In view of the

technical difficulties and the expense involved in the supply of a large volume of air in the form of minute bubbles, Messrs. Haworth and Hodgkinson attempted to treat sewage by mechanical agitation in the presence of previously activated sludge, relying on surface absorption for the oxygen supply. Experiments begun on a small scale in 1916 were so successful that a large plant was completed in 1920 and had been in operation when the paper was presented for more than five months. The plant consists of a single large aëration tank about two hundred feet long, seventy-five feet wide with a capacity of approximately three hundred fifty thousand gallons. It is divided by longitudinal walls into eighteen compartments four feet wide, forming when taken together a continuous channel 3,544 feet long. At the center of the tank there is in each compartment a paddle wheel ten feet in diameter which at a rate of fifteen revolutions per minute produces a minimum velocity of 1.7 feet per second in the channels. The sewage thus circulates round and round the channels with a constant inflow at the end and outflow at the other.

The outflowing sewage passes through three small retention chambers where a portion of the sludge settles out at reduced velocity and returns directly to the aëration tank; and thence the effluent passes to three settling tanks of the Dortmund type. Amounts of sewage varying from 250,000 to 500,000 gallons per day have been treated in this plant and although the sewage is exceedingly strong, the results have been most promising. Nitrification is not pronounced, but the suspended solids have been reduced to a low figure and the effluent has been consistently non-putrescible.

It would seem that this work at Sheffield is a contribution of the first importance to the art of sewage treatment, the first really fundamental improvement that has been made since the activated sludge process was worked out at Manchester. The results obtained at Sheffield, and elsewhere where this process must no doubt be tested, will be watched with the keenest interest by sanitary engineers.

---

### Pirquet Blazes Trail for New System of Nutrition

**P**OSSIBLY the latest word in infant and child feeding was brought out by Von Pirquet and his associates of the University of Vienna. He advocated and used a system of feeding whereby large numbers of children could be supplied with the necessary food according to their state of nutrition and whereby malnutrition could be remedied on a large scale. The system used by

Pirquet is based on measurements of the sitting height of the child, a unit that was found many years ago to bear a direct relation to the intestinal area. Pirquet standardized it both theoretically and practically and has made use of it on a large scale. Physicians who have recently returned from Europe claim that had it not been for Pirquet's system of feeding, Hoover's work might possibly have been a failure as far as European children are concerned.

Recent suggestions made in medical literature to employ the Pirquet system of feeding in this country have met with favor in some quarters and with disfavor in others. The great opposition to the Pirquet system is that we would have to undo the present system of nutrition employed in this country and learn a new formula, something that is not accomplished very easily. Time will tell whether or not the adoption of the Pirquet system is practical in time of peace.

Whatever the outcome of further study in the subject, Pirquet deserves much credit for calling attention to a new system of nutrition. His work shows that the possibilities for research in nutrition have not been exhausted and that men with great minds and proper training may in time evolve a system of feeding that will be both accurate and simple.

---

### Selling Health Protection at Cost by Cooperative Effort

AS A RESULT of a report by the Committee to Study Community Organization for Self-support of Health Protection for Mothers and Young Children, a small district has been selected in New York City in which the Maternity Center Association, the New York Diet Kitchen Association, and the Henry Street Visiting Nurse Service by special arrangement for joint service are prepared to furnish a health-protection and visiting nurse service to residents of that district at six dollars per person per year. The project required the organization of the "Citizens Health Protective Society," composed of residents of the district, which purchases the professional health service from the nursing organizations for the benefit of its membership.

The service will include supervision of pregnant mothers, assistance at confinement (other than doctor's services), baby health service for children under two years, including regular examination, weighing and inspection, instruction of mothers and home visits; health supervision of children from two to six years, including health and nutrition classes and special advice to mothers; and visiting nurse service for sick persons of all ages. It is definitely understood that

no advice or examination will be made without consent of the family physician.

The citizens' society is democratically managed and is in charge of all finances. Cooperation has been offered by the many churches, schools, and social groups in the district and the plan is expected to be self supporting and a genuine community health service. The cost of the service is based on the 1920 expenditures of the three participating associations and on the general averages of birth, death, and sickness rates. As the experiment develops the citizens' committee may wish to set up a sales department where members can buy collectively material for mothers, infants and young children, also maternity and sickness supplies.

The project is in one sense an insurance scheme, managed entirely under local auspices, with members bearing the entire cost. The citizens' society merely contracts with the three organizations for the health protection and sickness care of its members. The plan offers untold possibilities for public health development which should be evidenced in the form of declining general death and infant mortality rates and reduced morbidity from childhood contagion. Health education of the public will be materially advanced and the consideration of social health insurance would naturally follow. Miss Ella Phillips Crandall is director and the project is fully outlined in the *Henry Street Nurse* of August and September, 1921.

---

### An Active Campaign to Increase Membership

THE American Association of Industrial Physicians and Surgeons has assumed the task of doubling its membership, the minimum objective if each member secures one recruit. Every member of the Association, being in the active practice of industrial medicine, should be full enough of his mission to render this disinterested service. There is no field which offers a greater variety of open problems to interest scientific curiosity, none in which intelligent application yields more spectacular achievement, and none which promises more in the way of broadening activities. More than twenty-five hundred physicians in the United States are specializing in industrial medicine. The demands of the field call for collective effort and for scientifically directed activities. The man who would credit the organization or whose work is a credit to the cause should identify himself with the American Association. It is desired that the men whose work renders them eligible will make early application for membership.

# HEALTH IN INDUSTRY

*Official Organ of the American Association of  
Industrial Physicians and Surgeons*

*Editors for the Association*

THOMAS CROWDER, M.D.

WADE WRIGHT, M.D.

*Officers of the Association*

C. E. FORD, M.D., *President*

C. F. N. SCHRAM, M.D., *Vice-President*

L. A. SHOUDY, M.D., *Second Vice President*

W. A. SAWYER, M.D., *Secretary-Treas.*

## News Regarding the Membership Campaign

BY WILLIAM ALFRED SAWYER, SECRETARY, ROCHESTER, N. Y.

**W**E ARE out for new members. Every day the mail brings us additional prospects. Are you doing your share?

What we propose to do is to tell every physician throughout the country who is eligible to membership in the Association what such affiliation may mean to him personally, what his duty is in the way of personal contribution to the medical knowledge in this special field, what it means in furthering preventive medicine and in raising standards of medical practice.

Make this membership campaign a personal affair. Well organized committees can accomplish much in the way of propaganda, but nothing that compares to the dynamic interest held by the individual when he has done his personal share of the work. Muster your best arguments, tackle your closest associate, or the man you know to be doing creditable work outside the fold, and bring them into the advantages of full membership.

A gain of twenty-five has been made since September, yet the campaign is just well under way. Things are humming around the Secretary's office these days, but it is a mild situation compared to the activity we hope to stir up during the month of February. We want every member "up on his toes," pushing this matter for all he is worth. Nothing succeeds without effort. Once we get a sizable membership, the usefulness and value of this Association is going to progress rapidly. We want every individual surgeon in it. Let's all get busy and carry the message

to our colleagues. All you need to do is to secure *one* new member; but many will doubtless want to do more. Some have done more already. How about you?

### New Membership List

Dr. R. V. Harris, 19 Gordon St. E., Savannah, Ga.

Dr. Edward von den Steinen, National Lamp Works, Cleveland, Ohio.

Dr. S. M. Coryell, 8113 Woodland Avenue, Cleveland, Ohio.

Dr. D. B. Wells, 580 Asylum Street, Hartford, Conn.

Dr. R. B. Crain, Eastman Kodak Co., Rochester, N. Y.

Dr. B. J. Slater, Eastman Kodak Co., Rochester, N. Y.

Dr. E. W. Reeve, Equitable Life Assurance Co., N. Y. City.

Dr. L. A. McAlpine, Portsmouth Cotton Oil Refining Co., Portsmouth, Va.

Dr. C. A. Swan, Halle Brothers, Cleveland, Ohio.

Dr. T. Lyle Hazlett, Westinghouse Electric Company, Pittsburgh, Pa.

Dr. Douglas T. Davidson, General Chemical Co., Marcus Hook, Pa.

Dr. Sterling C. Basney, Pennsylvania R. R. Co., Glenoiden, Pa.

Dr. James F. Bowen, U. S. P. H. S., St. Louis, Mo.

Dr. Henry C. Schorr, 3707 Ellis Avenue, Chicago, Illinois.

### Applications for Membership

Dr. L. St. John Hely, Richmond, Cal., recommended by Dr. U. S. Abbott.

Dr. J. S. Alley, Midvale, Utah, recommended by Dr. A. J. Hoosomer.

Dr. C. E. D. Lord, Ely, Nevada,

recommended by Dr. R. A. Bowdle.

Dr. T. O. Boyd, E. St. Louis, Ill., recommended by Dr. L. G. Harney.

Dr. W. F. McNary, E. St. Louis, Ill., recommended by Dr. L. G. Harney.

Dr. Clarence H. Kilker, Cincinnati, Ohio, recommended by Dr. Carey McCord.

Dr. H. S. Reynolds, South Manchester, Conn., recommended by Dr. Robert Knapp.

Dr. M. A. Austin, Anderson, Ind., recommended by Dr. F. L. Rector.

Dr. F. G. Barr, Dayton, Ohio, recommended by Dr. F. L. Rector.

Dr. D. Brougham, Syracuse, N. Y., recommended by Dr. F. L. Rector.

It is with regret that we announce the resignation of Dr. Edward Gotchy of Chicago, who on account of a protracted illness has been compelled to give up industrial work.

# Length of Work Day and Industrial Health

## The Personal Equation is Always the Variable that Upsets Stereotyped Calculations

By REYNOLD A. SPAETH, PH.D., ASSOCIATE IN PHYSIOLOGY, SCHOOL OF HYGIENE AND PUBLIC HEALTH, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

SCIENCE has been called the modern man's religion. When he finds himself entangled in a particularly complicated problem, instead of consulting Aristotle or the Scriptures, he appoints a committee to gather statistics. This expedient is frequently successful. There is something formidable about an array of figures. Graphs and charts give a dazzling impression of irrevocability and expert knowledge, especially when backed by a dozen integration symbols. Whether the particular problem can really be solved by the machinery of science is rarely asked.

The question of the length of the industrial work day is a striking illustration of the merciless application of scientific method.

Apparently convincing figures have been gathered to prove the greater efficiency of the twelve, ten, eight, or even six hour day in various industries. The key to a better understanding of the situation seems to lie in that word "efficiency." The moment we apply the efficiency criterion we may ask: "But efficient from what viewpoint?" If you chance to be an operator or a production manager or a stockholder you naturally concentrate on output and profits. Or, again, you may be an active trade unionist or a member of some cooperative society, in which case your primary interest lies in high wages and an attractively low sale price to the consumer. In other words, "efficiency" is purely a scientific problem when applied to the behavior (i. e., power consumption, etc.) of inanimate machines, but the moment it involves the health and happiness of human beings a moral factor is introduced and the problem passes from a purely scientific to a social-ethical level where science cannot and dare not follow. The failure to distinguish clearly between these two levels—the unmoral and dispassionate scientific level and the social-ethical one, has led to a vast amount of controversy and misunderstanding. An illustration will clarify the point.

Last year the Women's Joint Legislative Conference asked a certain association of merchants to endorse an

*No precise rule of universal application has been formulated to determine the nervous fatigue of the workman, nor does the degree of fatigue usually denote a given amount of work done.*

*Intense effort can provoke fatigue before any considerable amount of work is done. Prolonged hours of labor may merely distribute a fixed amount of energy over a longer period, or increasing inertia from prolonged effort overcome apparent advantage in the longer day.*

*To attain the maximum yield from labor is to proportion the elements of work to the physiological requirements of the workman. The speed of economical work is determined by precise and specific studies in each industry or, it may be, in each shop.*

eight hour bill. The Committee of the merchants' association insisted that the only basis for endorsement by them would be the proof that the health of women was disastrously affected by nine hours of work and would be protected by eight hours, and that production would be as great and as cheap in eight hours as in nine. Those of you who have had experience with physical examinations will appreciate that exact evidence of actual injury resulting from one extra hour of work per day is a hopeless thing to prove. We have troubles enough trying to run down that elusive and academic individual, the "normal" man or woman. Human variation is far greater than the merchants' committee realized. The work day problem to them was purely a question of cost of production. The illustration is of interest chiefly in showing how completely we may miss the real issue and yet how safe and reasonable we feel, by blinding our eyes with the glamour of scientific method.

Another example of the confusion that arises from concentrating on the statistical aspects of the problem is

afforded by the recent publication of the United States Public Health Service Bulletin No. 106. In this case a study was made of the relative efficiency of an eight and a ten hour plant. The verdict was in favor of the eight hour system. Efficiency, as usual, was undefined. This bulletin has called forth a storm of criticism. In a special report (No. 14) the National Industrial Conference Board believes to have demonstrated without question that "the conclusions (of Bulletin 106) are essentially unscientific and not justified by the data offered" since the two plants are not fairly comparable; and the basis of experience is too small to justify comprehensive conclusions applicable to industry in general.

In reviewing the Public Health Service Bulletin in the *Journal of Industrial Hygiene* Dr. Drinker asks:

(1) Can a comparison of two factories under different managements (and at different wage levels, we may add) give any valid information as to the proper length of the work-day?

(2) Is it sound procedure to neglect practically entirely the medical and sociological aspects of a problem so important and so pretentiously undertaken as the one in hand?

The presentation strikes one more as a well organized argument for eight hours of work than as a thoroughly dispassionate display of the facts at hand.

The criticism and counter-criticism may be followed further in Miss Goldmark's response to Dr. Drinker's review in the *Journal of Industrial Hygiene*. You will also find there a warm controversy between two of the Government's scientific investigators, one of whom comes to the defense of the worsted ten hour plant where he is or has been employed. I mention these matters in order to call attention to the exceedingly live nature of the problem.

The question now arises as to why there should be such a lack of agreement among the various investigators. If the problem of the "proper" length of the work day were really open to scientific proof one way or the other, such proof ought by this time to be forthcoming. In my opinion the difficulty is a fundamental one. We

have been fooling ourselves into believing that by trundling out the impressive paraphernalia of science we must necessarily arrive at the correct conclusion of the larger question. It is our old problem of the scientific vs. the social-ethical level. Evidence on the scientific level will not prove the rightness or wrongness of a problem which strikes at the very foundation of our social structure. We Americans are hard headed, practical people. We want to be shown. So we turn our modern trick of gathering statistics. I am convinced, however, that our friends, the British trade unionists, are ahead of us when it comes to understanding the real nature of the work day problem. Just thirty years ago when the eight hour movement was a more live issue in England than it has yet become in this country, Sidney Webb wrote as follows:

The demand for shorter hours of labor has arisen among the working classes, not so much from the conviction that their present hours are injurious to health—though that in many cases is the fact—not so much from the theory that shorter hours mean higher wages—though that theory is in the main sound—but from the strongly felt desire for additional opportunities for recreation and the enjoyment of life.

I should not care to leave the impression that science has nothing whatever to contribute to the work day problem. Indeed I believe we can even go so far as to predict quite accurately what the application of scientific methods will demonstrate. Considered from a straight production viewpoint there will certainly be figures proving the advantage of shorter hours in some processes and industries, and of longer hours in others. These figures will vary from plant to plant and from process to process. One of the chief determining elements will be the percentage of human contribution, the "handling time" of the Taylor school. Long hours are certainly an advantage (again from the production viewpoint) where we deal with 90 to 100 per cent machine processes. Such jobs cannot be speeded up and shortening of hours means decreased output as Dr. Vernon clearly showed in his final report of the Health of Munition Workers Committee. Maintenance of production must here be secured either by additional machines or by a shift system. This problem, as Drury has recently shown, can be laid squarely across the shoulders of management.

Even in the most painstakingly careful studies like that of Ernst

Abbé at the Zeiss Optical Works in Jena—which comes as near being really scientific as any that has been made—it is difficult or impossible to evaluate the contributions of actual shortened time and increased efficiency of plant methods. And even more elusive is the psychological influence of shortened hours on the workers themselves.

#### Work and Plant Production

Science thus offers no answer to the general question, what is the proper length of the work day. If you ask: "Can I shorten hours in my plant and maintain production and profits and perhaps release the will to work among my employees?" science stands ready to help. The tacit admission on the part of a plant management that greater facilities for recreation and relaxation for its employees may be a sound long time investment is virtually a recognition of the larger social-ethical problem. How completely this larger problem remains unrecognized is strikingly illustrated by a careful reading of the National Industrial Conference Board's Research Report No. 32 on "Practical Experience with the Work Week of Forty-Eight Hours or Less." At first blush one gets the impression that the work week of forty-eight hours or less is a failure, for in 87 per cent of the establishments studied the weekly output of workers decreased. A closer study of the facts shows however, that production was frequently determined by the speed of automatic machines or working conditions were not what they might have been, resulting in a large turnover. It is a simple thing to blame the failure of a shortened work week upon the lessened hours of labor. In reality the fault frequently lies with the management or employees or with both.

In spite of a widespread appreciation on the part of labor of the desirability of a shorter work week, the basic rather than the straight eight hour day has received by far the greater support. The basic eight hour day permits overtime at time and a half wages. In other words, by failing to endorse the straight eight-hour day, as was the case at a recent convention of the American Federation of Labor, labor has weakened its whole position. The advantages of the basic eight hour day are purely economic. It provides a mechanism for increasing wages but fails completely to contribute towards the solution of our fundamental problem. In some quarters the incon-

sistencies of labor's position are beginning to be appreciated. Mr. Hillman of the Amalgamated Clothing Workers of America has been steadily pushing ahead in the direction of a straight eight hour day. He, for one, realizes the advantages of eliminating overtime.

This points out certain tendencies that have crept into our thinking on the work day problem. Some may wonder what bearing these remarks have upon industrial health. The relation is fundamental. Industrial health is not limited to human accident and illness statistics. There is a larger health of industry itself measured in terms of stability and clear thinking. The maintenance of this larger industrial health is our greatest safety problem. It challenges the best efforts of labor, capital and management.

#### Cost of Health Service in Industry

Various studies have been made of the cost of health service in industry, the last being that of the survey of the industrial medical field in Cleveland, O., in 1920. The present pamphlet published by the National Industrial Conference Board, May, 1921, records results largely from plants with organized medical departments. In the plants reporting a total of 764,827 workers were employed. Two or more plants in each of the twenty-three industries submitted reports.

The report states that the earliest recorded effort concerning the health supervision facilities in industry was made in 1879. Only nine firms reporting had health supervision previous to 1900, while 164, or 86.7 per cent established the service in 1910 or later. The largest number introduced it in 1916, and the next largest number in 1919.

The average cost as shown by the investigation ranges from \$1.84 per employee per year in the tobacco industry, to \$24.40 in the mining industry, averaging for all industries reporting \$4.43 per employee per year.

There has, of course, with the development of health supervision, come a much greater increase in the scope of work. While medical service was primarily developed to care for industrial accidents, the work today goes into all the departments of the plant and extends even into the home and community life of the workers.

The report covers the cost, the staff organization, equipment and the scope of work.

# Contagion in Industrial Establishments

## Prevention Connotes Measures Exactly Fitted to the Direct Causative Factors

BY D. L. RICHARDSON, M.D., SUPERINTENDENT, PROVIDENCE CITY HOSPITAL, PROVIDENCE, R. I.

VARIOUS industries, particularly large mills and factories, are becoming interested in the health of their employees. It can hardly be termed wholly an altruistic move but is plainly an indication that business men realize it pays to keep their employees well. It is certainly a commendable movement viewed from any standpoint.

The control of infectious disease resolves itself into tracing individual clinical cases, and the detection of carriers. The more intimate the contact of public agencies with the general population, the better will be the reporting of frank and suspected cases of contagious disease. To such agencies will go families suffering from mild illnesses for which they would not consult a private physician, and it is these mild cases which play so significant a part in the spread of disease. For this reason the public health officials welcome the employment in industries of physicians and nurses.

It is quite a common practice for the larger establishments to have a doctor or nurse, or both, to look after the health of the employees, a wise provision which should be universally adopted. Rather than being a financial burden, it becomes a distinct asset to any company to keep its employees well, for lost working days of employes is often a serious handicap to the company, particularly in the care of skilled mechanics and supervisors.

It is not the place to more than mention here the importance of fresh air ventilation and safety devices.

Safe water for drinking purposes should be distributed so that employees can reach it without too much loss of time. No common drinking cups should be tolerated. Either drinking fountains or individual cups should be supplied at a faucet or tank.

Sufficient toilet facilities, preferably with split seats, should be provided. The toilets should be provided with lavatories without plugs and the water turned on by a foot or knee device so that one can wash in running water. If hot and cold water are supplied they should be piped so

that both are delivered through a common spout. The common cake of soap should be replaced by a liquid soap which makes a good lather and is delivered from a container with an escape valve in the bottom. The hands should be dried on paper towels or on individual hand towels. All processes of manufacture which require putting things into the mouth should be prohibited. Offices should have moisteners for stamps and sealing envelopes and notices should be posted advising employees to avoid putting anything in the mouth except food and drink, and these with clean hands.

Ideally all employees should be examined for infectious disease before entering upon their duties. This recommendation is aimed particularly against tuberculosis and venereal disease. Such a procedure is hardly practicable although something may be done along this line. It is hard to exclude tuberculosis subjects yet it should be done if the case is an open one, and the time is not far distant when the employees themselves will insist upon it. Less compunction need be exercised in excluding those infected with venereal disease and the importance of syphilis stands first. This disease because of the throat and mouth and skin symptoms is a menace to other employees, any of whom may be innocently infected.

The doctor and nurse should have regular hours and to them should be sent all who are ill or not feeling well. Most conditions found will not be infectious but when they are the doctor should be ready to recommend what should be done to protect the rest. An employee sick with an infectious disease should be excluded until he is well, or until the physician feels it safe for him to return. It is of much value to have the nurse visit the homes of employees who are out more than two or three days, to ascertain whether the employee is sick and the nature of the illness.

When an infectious disease does develop the factory doctor should inspect daily those in most intimate contact with the sick person that he may be able to exclude any others who are infected, at the earliest possible

moment. These examinations should extend over the incubation period of the disease in question.

Smaller establishments may have a nurse alone but she should be under the direction of some physician who may be called for advice. Several shops may combine and have one doctor and nurse.

Factory help need constant health supervision because of the nature of their work and the character of the employees.

Cooks, waiters, bakers, those who dispense drinks should all be licensed and examined at least twice a year, a license card issued for a six months period, this examination to be done by the health department with painstaking care. Each applicant should be stripped to the waist so that the chest, abdomen and skin may be examined, as well as the eyes, mouth, and throat, chest, etc. The men should be examined for venereal disease routinely, and the women if there is a suspicion. It has been found that this examination, if courteously and well done, and particularly if the physician points out any physical defects which need remedial measures, these employees will not object. They will appreciate that they are getting a little free medical advice which may be of much importance to them.

In some places it is wise to make a Widal test on every one applying for license. Urine and feces should be examined if the medical history gives an account of typhoid fever, or if the Widal is positive.

The routine Wassermann is probably not necessary. However, it should be taken whenever any suspicion exists of infection. All those without lesions may be allowed to work as long as they are under the constant observation and treatment of some physician or clinic.

### Roentgenology in Brazil

The Ministry of Public Instruction in Columbia has arranged an x-ray course which will include technic, diagnosis, and treatment. There will be hospital facilities for use of the students. Dr. Richard Andrés will have charge of the work.

# Accident Prevention from a Medical Viewpoint\*

BY W. H. LIPMAN, M.D., MEDICAL DIRECTOR, SWIFT & Co., CHICAGO

**T**HIS is an age of prevention—prevention of disease, accidents, strikes, unrest, panics, war, waste, profiteering, and famine. Prevention is the slogan of the day. The superiority of the prevention of all things undesirable as compared with their elimination or the correction of their evil results, is the outstanding teaching of the last three or four decades.

The old adage that "an ounce of prevention is worth a pound of cure" is too mild for these times; that a grain of prevention is worth more than a ton of cure would more nearly express the spirit of the day.

Medicine of today is largely a science of preventing disease. When the cause of a disease is discovered, more energy is devoted to finding means of preventing it than is devoted to the attempt to develop a cure for it. Perhaps the best evidence that prevention of disease is looked upon as of greater importance than the cure is the fact that for the past ten or fifteen years the activities of the Federal, state, and municipal health departments have been very greatly broadened. Their work has become much more comprehensive. Another indication equally as convincing of the value of prevention is the great development, in the past decade, of industrial medicine, one of the newest but by no means the least important of the medical specialties, which has already established for itself a permanent place among the branches of medicine.

## Constructive Work in Industry

Industrial medicine is almost entirely a preventive undertaking. It aims, first of all, to prevent placing the wrong man at a given job or giving the wrong job to an applicant for employment all of which is to the benefit of the applicant, the working force and the public. Second, it attempts to prevent the spread of illness among employees either by periodic physical examination or by early treatment of sickness. Third, by promoting efficient care of accidental injuries, it prevents complications and reduces disability to a minimum. In reality this is nothing more or less than safety work; safety for

the employee; for his family, for the employer and for the public.

It is not necessary these days to apologize for, or to attempt to prove the value of, safety work or what it has accomplished in the past quarter of a century. Every person who reads, every person with his eyes and ears open knows that lives have been saved, that suffering has been spared and economic waste diminished.

From time to time, tables are issued to show the economic and monetary value of safety work. We are shown that so many lives have been saved, therefore, since every life is considered to be worth a certain number of dollars and cents to the community, the country has been saved a certain sum of money, and disability is figured on a corresponding basis. While all this is very impressive, I believe it does not commence to tell the story. Only those who are actually and actively engaged in safety and accident prevention work and industrial medicine fully appreciate what an accident means to the man who is injured and to his family, and what prevention of accidents really amounts to.

When we speak of safety work, mechanical safety appliances immediately come to our mind. Many of us look upon safety work as merely a matter of guarding machinery and tools, railings for stairways, or signs for crossings, and a thousand similar devices. All these have their place and are extremely valuable in preventing accidents, but to my mind, it is one thing to provide these and quite another and more important thing to imbue your men with the will and the urge to use them. Unless you can instill in the minds of the workmen a belief in you and your safety work, your mechanical appliances will be of little value. Of course, one way to induce men to use safety appliances and to be careful at their work is to educate them to the value of safety by means of signs, placards, booklets, and safety campaigns and rallies, and unquestionably they all help, but this is not the most important phase, in my opinion, of safety work. The men must be convinced that the company is in earnest in all its safety work and that it is undertaking it, first of all for their benefit, and secondarily, for the advantage of the company; in

other words, for their mutual good, and it is to the best ways and means of accomplishing this, as viewed from the medical department, that this paper is devoted.

Everyone agrees nowadays that the foreman is looked upon by the workmen as the representative of the company, and whatever he does is interpreted by them as the will or policy of the company. Next to the foreman in the eyes of the men, the plant doctor represents to them the opinion of the company in matters touching accidents and illness. Therefore, success of safety work depends largely on the conduct of the foreman and the doctor, in the way accidents are prevented and handled after they occur. We cannot expect men to believe in safety work if they find their foreman never shows any signs of interest in accidents that occur in his department.

## The Human Interest

Aside from the opportunity the foreman has for safety work by showing and convincing his men that he is interested in safety just as in any other activity in his department, there is another field by which the foreman can bring home to his men his interest in safety, and that is the interest he displays in the injured man after the accident has occurred. The foreman must see that no matter how slight the injury, the injured man must go to the doctor's office or the first aid room, as the case may be, at once. It is true, some men with trivial injuries do not see the necessity for treating them and it requires considerable tact on the part of the foreman to explain to them why it is necessary to do so. The object will be defeated and more harm than good will be done, if the foreman orders the man to go to the doctor's office gruffly, without explaining in a simple dignified way the necessity for it, because the next time the men have slight injuries they will hide them from the foreman.

After the man has been to the doctor's office and received treatment and returned to work, the foreman will make a serious mistake if by his attitude he gives the impression that the man committed a crime by receiving an injury. If the man is made to feel that by having met with an accident he has injured the safety stand-

\*Read before the Tenth Annual Congress of the National Safety Council, Boston, Mass., September 27, 1921.

ing of the department, and therefore got himself in bad, he will not be a very enthusiastic booster for safety.

Those of you who have had experience in the care of accidents know we are all human and expect consideration and sympathy and recognition when we are in good health, and that we expect just a little more of these things when we are ill or when we are injured. Imagine how you would feel if, after you had worked for a company for a number of years and become injured and are sent to a hospital or home, you are dropped there and your foreman never shows any signs of trying to find out how you are getting along: you would soon lose whatever respect you had for the foreman and for the company. On the other hand, if the foreman either calls on the injured employee himself, if consistent with the injured man's length of service and other conditions, or else sends one of his fellow workmen to tell the injured that he wishes to know how he is getting along and inquires when he will be back to work, it will not only help relieve the injured's mind and make the weary days in the hospital shorter; but he will become a booster for the company and the foreman in all their undertakings including safety work.

So far we have discussed the things that a foreman can do to prevent accidents, but that is not all there is to safety work. Sometimes accidents happen to accidents which are more serious than the original injuries. Accidents may happen to accidents in two ways. Firstly, by not treating the injuries at all and secondly, by mistreating or mistreating them.

We have already seen how important it is that all injuries receive prompt treatment. When a slight injury occurs the foreman is strongly tempted to try to treat it in the department and in many cases this will meet with the favor of the employee. By doing so the foreman and the patient both assume a great responsibility because while it is true a great many slight injuries get well without any treatment whatsoever, one can never tell which one of them will cause serious trouble or even terminate fatally. There is no question that neglected slight injuries, cuts, wounds, etc., are the cause of a great share of disability, temporary and permanent. We would particularly issue a strong warning against attempts on the part of foremen or other laymen to try to remove foreign bodies from the eye. A great deal of unnecessary suffering, disability and, ac-

ording to some reports, even loss of sight has been caused by infection following unsuccessful attempts to those incompetent to do so to remove foreign matter from the eyes. Another practice often followed by serious trouble is for someone in the department, the foreman or a fellow workman, to advise the injured to use his favorite remedy on his injury because it cured someone about fourteen years ago or because a friend of his once knew somebody who had a friend whose injury was healed overnight by a certain preparation.

#### Not a Panacea

There is no cure-all for injuries any more than for sickness. Healing is delayed, serious complications brought on, and loss of limb at times caused by meddling treatment at the hands of the unqualified. I recall the case of a young woman who lost the index finger from gangrene caused by soaking the finger in "carbolic water" on the advice of a friend.

Of course, it is impossible to entirely eliminate this danger. People will always give advice to the sick and injured in good faith and with the best of intentions, but the foreman can do a good deal to reduce it to a minimum. He can ask the injured from time to time how he is getting along; whether he is going to the plant doctor's office for treatment or to the outside consultant, as the case may be. In that way the foreman will learn whether the injured is getting proper treatment or is using or doing something of doubtful value.

In the beginning of the paper we stated that the plant doctor is looked upon by the men as representing the company in all matters concerning accidental injuries. The importance of this cannot be too strongly emphasized and it can be seen at once that the manner and spirit with which the doctor treats the patient will not only determine to a great extent the success of the treatment but they will either make a friend or an enemy of safety out of the injured.

If the injured is treated inconsiderately, roughly and is jostled around mercilessly, he cannot be expected to entertain a great deal of enthusiasm and confidence in the plant safety work. He reasons that his company cannot be very earnest in its safety campaign if it does not care how the men are treated after they are injured. The doctor must treat the injured employees like patients and not like "cases" in whom his only interest is to make an accident report. An

injured man is hypersensitive, or, as a prominent surgeon once put it, he is an insulted man, because his sensibilities have been outraged and he must be handled accordingly.

If the injured is made to feel that the doctor is doing his best to hasten his recovery and promote his comfort, he will gladly submit to the necessary treatment and will later encourage the other men to go to the doctor's office for treatment with all injuries and do so himself. The doctor must so conduct himself in the treatment of the injured that he will inspire in the men not only a confidence in the professional ability but with the conviction that he is their friend and counselor. He must make them feel that they can come to him with their accidents or with their claims for compensation and receive the best kind of advice; advice that is fair both to him and to the company. Space does not permit going into detail as to what the industrial physician should or should not do in the course of treating industrial accidents. In this I do not refer to the purely technical or professional treatment. There are a thousand and one things that go to make up the successful and valuable industrial physician besides his professional skill and learning.

The way he handles the injured parts, how he cleans them, what he does to relieve the patient's mind of worry and fear of serious complications, the air with which he notifies the injured's family of what happened to him, the frequency of his calls on the patient at home or in the hospital, his absolute adherence to all promises made to the patient and countless other things are all as important as his knowledge of medicine and surgery.

In closing it is to be emphasized that my fairly extensive experience in the practice of industrial medicine indicates safety work to be one of the basic needs of industry. The safety campaigns of the past ten or fifteen years have been a great success in that they have materially reduced the number of serious accidents with benefit to the employees and the employers, the value of which cannot be figured in money. Complete safety work is composed of two parts, one as indispensable as the other: (1) A more extended use of mechanical safety devices; and (2) a recognition of the importance of the human element before and after the accident, without which mechanical protection can only prevent a small number of accidents.

# An Industrial Emergency Hospital

BY BERT T. BARNES, MORSE DRY DOCK & REPAIR COMPANY, BROOKLYN, N. Y.

**A**N INDUSTRIAL emergency hospital equipped with facilities far superior to the ordinary organization of its kind is that at the ship repair yard of the Morse Dry Dock & Repair Company, Brooklyn, N. Y. A building of five large rooms and a sun porch is devoted exclusively to hospital purposes. Two of these are fitted up with a complete equipment, including sterilizers, dressings, surgical instruments, cots, etc., while the outside equipment consists of an ambulance, stretchers placed in the

the injury is perfectly healed and he is back at work again. This is not always easy, for there are some men who get one or two treatments and then fail to show up, thus running the danger of infection or blood-poisoning. In these cases they are immediately asked to report at the hospital and, if necessary, an automobile is sent for them.

In the cases of men who when slightly injured neglect to go to the hospital for treatment, the foremen in the different departments report the injuries and these men are at once asked to present themselves for treatment. The Morse Company is intent on giving the best possible care to every employee. Not only is it solicitous for the welfare of each one, but the company believes it is financially good business to have every employee in the best possible health.

To insure the best medical and surgical attention for its employees, the company retains the services of the leading specialists in the several different branches, such as surgeon specialists, an eye specialist, a dental expert, an ear specialist and an x-ray specialist. Whenever the necessity arises, an employee is at once put under the care and treatment, according to his injury, of one of these specialists.

For most serious cases there is available the use of a semi-private ward of six beds at a nearby hospital, where patients from the yard can

be given special attention. During the progress of treatment they are supplied with magazines, games, and other means of whiling away the stay at the hospital.

Established just prior to 1917, the yard emergency hospital has more than proved its worth, treating during the rush of war activity more than six thousand cases a year and at the present time averaging two thousand five hundred to three thousand cases a year.

Previous to the establishment of the present system, a truck load of ten or twenty men suffering from lacerations and minor injuries was sent to a nearby physician for treatment every day, while the more serious cases were sent immediately to the hospital. Under this plan, a speck of metal in the eye or a minor cut often did not receive immediate attention.

Now, in connection with its continuous safety campaign, the employees' magazine, the *Morse Dry Dock Dial*, constantly urges the men to get medical attention for even the slightest injuries and not take chances of infection, thus cooperating in this campaign with both the hospital staff and the management.

In addition to their work in the hospital, the nurses act also as visiting nurses to the families of the employees, when occasion arises. This activity has met with the highest appreciation from the men and their families.

In the special services a dental expert is retained, and an oculist, aided by the x-ray, takes immediate care of all eye injuries, major or minor.

shops and various points throughout the yard, and basket stretchers for raising injured men out of ships' holds and lowering them safely over the side.

The emergency hospital is open both day and night so that medical attention is at all times immediately available. A visiting physician is in attendance every day and treats the more serious cases, while two nurses are on duty during the day and one at night. In addition, a clerk keeps a record of every case, so that those in charge of the hospital are always in touch with injured employees and the progress of their improvement.

A very important feature of the work is the follow-up or after-care. When an employee is injured, he is kept under proper treatment until

This interior of the Yards Hospital shows how complete are the arrangements and equipment. The emergency hospital is open day and night, and is supplemented by outside equipment.

# Iodin as a Wound Disinfectant—Recent Research

## Results of an Investigation by the Conference Board of Physicians\* in Industry

BY FRANK L. RECTOR, M.D., SECRETARY, NEW YORK CITY

THE use of tincture of iodine as a disinfectant for the skin, particularly for the field of operation, and for the treatment of injuries came prominently before the public about 1905. There is considerable discussion in the medical press as to who should be given credit for introducing it to the profession. Among the many claimants for the honor Cannaday,<sup>1</sup> Woodbury,<sup>2</sup> Dannreuther,<sup>3</sup> and Grossich,<sup>4</sup> should probably be considered first. Grossich of Germany is conceded by many to have been the first to write comprehensively on the subject, and later writers refer to his article in *Zentralblatt für Chirurgie*, No. 44, p. 1289, October 31, 1908, as definitely establishing this practice.

Woodbury used iodine in 1906 in army practice in the Philippines, and wrote at some length regarding its use from 1907 to 1912. Cannaday and Dannreuther used it in this country in their general practice during the early part of the decade 1900-1910.

The tendency among those who first began the use of iodine was to use the undiluted tincture, and instances were noted where 20 per cent solutions were used. In this country Boveé<sup>5</sup> and Neate<sup>6</sup> seem to have been the first to publish results of experiments looking toward the employment of more dilute solutions. In England Turner and Catto<sup>7</sup> did work contemporaneously with Boveé, and they arrived at the same practical conclusion, viz.: that a 3 or 3½ per cent alcoholic solution was the best to use for general skin disinfection. The use of a solution of this strength accomplished sterilization in a few minutes.

Boveé used the plain diluted tincture while Turner and Catto used a mixture of the following:

Prepared iodine... 30 grams  
Potassium iodide... 40 grams  
Aque dest. .... 500 cc.

\*The Conference Board of Physicians in Industry is a voluntary, informal association of medical directors in industrial plants, organized for the exchange of ideas and experiences and the formulation of suitable standards and methods in industrial medical and surgical practice. The Board acts as advisor to the National Industrial Conference Board on medical problems in industry.

Before using, this solution was diluted to 50 per cent strength with methylated spirit, making a solution of 3 per cent iodine strength.

Boveé found by his experiments that "skin may be kept sterile indefinitely, or at any rate for thirteen days, that pubic hair can be kept sterile five days with a 3.5 per cent alcoholic solution of iodine." He states further that 3 per cent strength is the weakest solution safe to use.

Neate, who carried out the experimental work for Boveé used three methods: (a) scrapings from sterilized skin surfaces were taken at definite intervals following application of different strengths of iodine and while the operation was going on, and placed in tubes of culture media; (b) small strips of skin were excised from the edges of the incision and transferred to tubes of liquid culture media under conditions similar to (a); and (c) pieces of sterile catgut sutures were passed back and forth beneath the superficial layers of the skin, the sutures not penetrating sufficiently to cause bleeding, and then removed to tubes of culture media. It was found that all tests made with a 3 per cent solution or stronger gave sterile results.

Orr<sup>8</sup> writing in 1913 quoted the French surgeon Walther<sup>9</sup> to the effect that in seven minutes the iodine (strength of solution not given) deposited on the epidermis sterilizes the deepest layers of the skin. Woodbury says that "for ordinary practice and in emergency surgery the 2 per cent tincture of iodine will be, however, the antiseptic method of choice." He says that use of 10 per cent tincture has caused edema of the glottis and post-operative pneumonia.

Kinnaman<sup>10</sup> found a 0.2 per cent to 1 per cent solution to be markedly antiseptic, and far superior to bichlorid. A 2 per cent solution killed streptococcus pyogenes in two minutes. He considers a 0.5 per cent solution strong enough for all antiseptic purposes. It is one quarter as toxic as bichlorid, does not coagulate albumen, is very penetrating, and is effective in a brief time.

Dannreuther said in 1908: "From my experience with iodine in hospital

and clinical work, I have been convinced that it is an agency of high germicidal potency, one of the most valuable antiseptics in our armamentarium, and endowed with remarkable penetrating power." He reported at the same time that he generally used the U.S.P. tincture (7 per cent), but that in certain cases he employed Elsberg's solution, a 20 per cent solution of iodine in alcohol and ether.

### Irritation Stimulates Healing

In 1908 Schantz<sup>11</sup> published an article in which he claimed that if a healing wound was subjected to slight irritation a much smaller scar would be left than if it was allowed to heal normally. He accordingly painted the wounds on the third and fifth days of healing with tincture of iodine, and large wounds were painted daily. By this means he stated that only threadlike scars remained even when the injury was considerable.

Those interested in the development of this subject up to the latter part of 1910 will find an excellent review by Wollheim<sup>12</sup> in the *American Journal of Surgery* for November, 1910.

### The Present Study

Little or nothing has been written on this subject since 1912 or 1914. In order to get some expression of present uses of iodine, particularly in industrial work, inquiries were sent to about seventy-five physicians asking what preliminary cleansing was done to wounds and what strength iodine was used. Their replies are herein discussed.

Replies were received from sixty-five physicians, all of whom were doing industrial work or surgery closely allied to industry. Of this number, 2 use 10 per cent solution, 18 use U.S.P. 7 per cent tincture, 21 use 3½ per cent (or 50 per cent U.S.P. tincture), 10 use 3 per cent, 3 reported use of 2 per cent solution. The other 11 physicians reported use of solutions of 4 per cent to 5 per cent strength. It is thus seen that only 20 used U.S.P. or greater strength, while 45 used a solution of 5 per cent strength or less.

A few of the men said they did not use iodine, or if used at all it was only sparingly used. One preferred camphenol, others used dichloramine-T, chlorazene, Dakin's solution, 7 per cent sodium oleate, picric acid 5 per cent, liquor cresolis compositus, hychlorite, 10 per cent calendula for large lacerated wounds, alcohol, solution of bichlorid 1:200 in 95 per cent alcohol + 2 per cent HCL.

Several of the physicians emphasized the importance of having the surface perfectly dry before iodine is applied. A damp skin surface interferes with the penetration of the antiseptic, and renders its use less efficient. Earlier writers laid stress on this same point. The most satisfactory method of preparing the wound area for iodine is to use alcohol and ether as final cleansing agents.

### Objections to Iodine

Some of the physicians who explained why they did not use iodine stated that it caused burns too frequently. Austin of Remy Electric Company said he had seen fifteen weeks disability from four iodine burns in 1920. Smith of General Electric Company is opposed to the use of iodine on punctured wounds and wounds with extensive skin abrasions. In the former the iodine tends to seal the mouth of the puncture and hold infectious material, and in the latter, a hard crust is formed which delays healing. He prefers the use of a 5 per cent picric acid solution for all but large lacerated injuries. Wainwright of D. L. & W. R. R. prefers washing the wound itself and adjacent skin with 7 per cent sodium oleate. Elliott of National Lamp Works prefers alcohol to iodine while Shipley of New York Industrial Health Bureau discourages the use of iodine as a routine first aid measure substituting therefor camphenol or similar compound. He does not object to its use by physicians or nurses in the dispensary or operating room.

Owen of the Bureau of Fire and Police, Philadelphia, uses dichloramine-T with paraffin gauze mesh. Driscoll of Hendee Manufacturing Company and Noland of Tennessee Coal, Iron, and Railroad Company also use dichloramine-T and chlorazene. Hastings of the Brill Car Company uses liquor cresolis compositus more frequently than iodine. Chattaway of Remington Typewriter Company uses a wet dressing of 10 per cent calendula in place of iodine on large lacerated wounds.

Sistrunk reports that the Mayo

clinic, while still using iodine, is also using a solution suggested about ten years ago by Tinker of Ithaca, N. Y., consisting of bichlorid of mercury 1:200 in 95 per cent alcohol, to which 2 per cent hydrochloric acid has been added. Wright of Harvard suggests that a dressing of bichlorid subsequent to the use of iodine is harmful. He also states that experience at the Massachusetts General Hospital shows that iodine burns can be avoided by using 95 per cent alcohol in place of water as the solvent.

### Preliminary Treatment

Gasoline alone or in conjunction with benzene or ether was used by twenty-three physicians. With four men soap and water was the agent of choice with the addition of gasoline or benzene if grease was present. Six men preferred tincture of green soap, three used Abbott's neutral soap. One each preferred alcohol, lysol, 7 per cent sodium oleate, liquor cresolis compositus, creolin, cresol, and apinol. Apinol is a pine oil and by its use the physician states that in his experience grease and machine oil are removed from a wound more satisfactorily than by any other solution.

A few reported the use of two or more cleansing agents in routine work, while others listed several agents that were used, but did not indicate conditions on which their choice was based. In this last group are mentioned ether, 1:1000 bichlorid solution, peroxid of hydrogen for dried blood, synol soap, and 1:5000 cyanid of mercury, in addition to those already listed.

### Conclusions

From the information summarized herein it would seem that the use of iodine as a skin and wound disinfectant still holds first place in surgical technic, particularly in the industrial medical field.

Such objections as were raised were against the danger of burns and the discomfort iodine caused rather than against its efficiency as a sterilizing agent.

As far as could be determined, for the past ten years little if any research work has been done on the use of iodine as a sterilizing agent in surgical work.

In spite of the great popularity attained by chlorine compounds in the treatment of war wounds, iodine still holds first place in the treatment of injuries in civil life.

The results of this survey indicate that the majority of physicians en-

gaged in industrial medical work prefer the use of a solution of 5 per cent strength, or less. The Conference Board of Physicians in Industry has since its organization recommended the use of a 3-3½ per cent solution (or 50 per cent U.S.P. tincture), and in the light of present experience feels that this continued recommendation is justified.

### Government Need for Workers in Rehabilitation

The United States Civil Service Commission states that there is urgent need for reconstruction assistants and aides in physiotherapy and occupational therapy, trained nurses, and physicians, to serve in hospitals and other establishments of the United States Public Health Service and the Veterans' Bureau, in the care and rehabilitation of men injured in the World War. The Commission has announced that it will receive applications for these positions until further notice. The applicants will not be given written scholastic tests, but will be rated upon their education, training, experience, and physical ability.

The Commission points out the importance of filling these positions promptly with the best qualified workers available.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from the Secretary of the Local Board of Civil Service Examiners at the postoffice or custom house in any city.

### Publish List of Foreign Language Health Pamphlets

A list of foreign language pamphlets on health, with the addresses of the organizations publishing them, is contained in *Foreign-Born*, November, 1921. "Health Customs and Superstitions of the Immigrant Mother" appears in the same issue.

# The Neuroses and the Industrial Commission\*

## A Clear Statement of Inducing Causes and the Remedy at Hand

By LEWIS J. POLLOCK, M.D., CONSULTING NEUROLOGIST, INDUSTRIAL COMMISSION OF ILLINOIS, CHICAGO

IT IS easy to define a square, a circle, a coin, or a box. One understands immediately what is meant by appendicitis or a fracture of the femur. It is not easy to define a neurosis, nor is it easy to understand what is meant by "traumatic-hystero-neurasthenia." In the former instances we are dealing with physical objective conditions; in the latter, with a more or less intangible, psychologic or philosophic consideration.

As an introduction let us state that for the purposes of this paper, by a neurosis we mean a condition of ill health not produced by physical change in the body or its organs, and which is not an insanity. Inasmuch as we are dealing with industrial medicine, the type of neurosis dealt with is traumatic. One speaks of such a disability as functional in contradistinction to an organic one produced by real injury.

### Emotional States Persist

An introduction to this mysterious condition was afforded the medical profession when it was observed that, following railway accidents, many peculiar symptoms occurred in the absence of external evidence of trauma. The condition was then termed "railway spine." Erichsen, who wrote on this subject in 1866 and 1875, later, termed it "concussion of the spine." Subsequent observation and study showed that no physical change was present, even on microscopic examination, and it was recognized, chiefly through the efforts of Charcot, that the patient presented the same symptoms as did cases of hysteria and, in short, suffered from hysteria. The terms "railway spine" and "spinal concussion" gradually disappeared, and for them was substituted "traumatic neuroses." As the hysterical nature of the disease was recognized, traumatic hysteria was commonly used, as were the terms "traumatic neurasthenia" and "traumatic hystero-neurasthenia."

One might subdivide the neuroses, artificially, into groups, as psychasthenia, neurasthenia, anxiety states,

hysteria, etc., etc. The greatest number of cases are those of hysteria and in it the conditions of cause and effect are common to all the neuroses. Therefore, for the sake of simplicity through the efforts of Charcot, that this discussion will be confined to "traumatic hysteria."

It is not difficult to determine the just compensation for the loss of an eye, or the amputation of a leg. The conditions having been found, it is only a matter of arbitrary percentages. Why is it difficult to adjudicate a case of hysteria? The difficulty is due to unfamiliarity with the symptoms, the nature, the cause, and the results of this condition, and further, to obscurity of the differences between hysteria and malingering, and the ignorance of means whereby hysteria may be definitely differentiated from real injury. Let us attempt to clarify some of these difficult questions. We will not consider any of the philosophic questions as to the psychologic mechanism of hysteria, nor even offer a definition. We will attempt to make the condition understandable by some description.

In the course of association with industrial medicine one becomes familiar with many symptoms produced by injury: pain, spasms, contractures, paralyzes, convulsions, etc. It may be said that in hysteria every symptom of every disease or injury may be found. We have loss of memory, delirium, confused states, and stupors. We may have paralysis of one or more of the extremities, spasms, contractures, convulsions, pain or loss of sensation, dizziness, blindness, deafness, loss of speech, vomiting, diarrhea, incontinence or retention of urine, and symptoms without end.

It is natural to ask if one is confronted with one of these symptoms how can it be shown that it is not due to real injury. Disease or injury of the body or its organs produces a disturbance of function of that particular part. This disturbance of function presents signs and symptoms peculiar to itself. The signs are constant, and are associated, one with the other, in a consistent and determined manner. For example, a paralysis of the hand due to an in-

jury of some of its nerves shows an atrophy in certain muscles and in these only, a paralysis in only these muscles, a loss of sensation in a certain constant part of the hand and definite changes of response to stimulation with electricity. An injury to the spinal cord produces constant and definite changes of the reflexes, paralysis of a sharply defined part of the body, loss of sensation of certain characteristics, and disturbances in muscle tone and bladder and rectal changes. So with every part of the body. In hysteria there will be found absent such signs as would necessarily be present were the symptom, such as paralysis, due to an injury or we would find signs and symptoms which are adventitious and could not be associated with such a paralysis as the result of injury. In short, it may definitely be stated that a careful examination by a competent observer can serve to differentiate an organic from a functional condition, a real disease or injury from a hysteria.

Naturally, one asks how is it possible to have a symptom such as a paralysis or even a pain, and yet not have any disease of the body or its organs? If a *risqué* story be told in the presence of ladies, it is common even now-a-days to observe them blush. This blush is not imagined, we see it, it is physical; and yet it is caused by an emotion. Similarly, if one is frightened, he may be stricken speechless and motionless, his hair stand on end, his heart beat fast, he may burst out in a cold sweat, and he may even have a diarrhea. Here, too, we are dealing with physical changes not due to imagination, injury, or disease, but to emotion.

### Suggestibility Heightened

Some years ago, amusement was afforded us by viewing the startling feats of hypnotists. A common enough trick was to make the cheek insensitive so that the subject felt no pain when a needle pierced it; or to produce a rigidity of the body sufficient to permit one to break, with a sledge hammer, a rock placed on the body of a man whose head and feet only were supported by chairs. In

\*Read before the Eighth Annual Conference of the International Association of Accident Boards and Commissions, Chicago, September 19-23, 1921.

such a hypnotic state any disability suggested to the subject would cause him to suffer from it. Hypnosis is produced by suggestion and just as a hypnotized subject may accept a suggestion and feel and act accordingly, so does an hysteric. Some of these suggestions come from the patient himself. If one fears disability he becomes introspective and attentive to his general sensations. None of you felt the collar about your neck until I now mention it; now you all feel it. Our skin is so sensitive that we can feel the lightest wisp of cotton, yet it is seldom that we feel our clothes. We become inattentive to such feelings as experience teaches us are of no consequence. If I were to assure you that the feeling of a collar about your neck is indicative of impending insanity, and you believed me, you would feel your collar all day long.

Much of the suggestion comes from without. Consoling, anxious, and over-solicitous friends and relatives, injudicious examinations by physicians, and reexaminations without end, conversations with attorneys, repetition of symptoms in court, observation of and acquired knowledge concerning other patients, all contribute to the hypothesized picture.

What is the cause of hysteria? Is it trauma or injury? Is it shock, great emotional disturbance, over-exertion, fatigue, or privation? Among the many lessons taught by the late war, many may be gleaned relative to hysteria. In this war, a new type of destructive agent was used, high explosive shells. There were observed many cases of peculiar nervous manifestations which were attributed to the concussion resulting from the explosion of shells close at hand. These cases were therefore called shell-shock.

Careful observation by trained neurologists soon showed that grouped among such cases were patients suffering from various well recognized nervous disorders not produced by the accidents of warfare; that the majority were suffering from hysteria. Here, therefore, was a huge experiment in hysteria. The first problem was to determine whether any possible physical change produced by the nearby explosion of high explosive shells was responsible for the hysteria. Evidently not, as the symptoms, tremor, paralysis, mutism, etc., were found to have developed in soldiers in training camps in the United States, on transports en route to Europe, in the S.O.S., back of the lines and on the way back to base

hospitals from the trenches. Such cases are even now developing among our discharged soldiers. It followed that the explosion of shells alone was not responsible nor was the privation, hunger or exhaustion.

### A Disorder of Conduct

Was it emotion? Apparently not; rarely were paralysis or other major hysterical symptoms observed on the battlefield itself. Only after some time elapsed did such symptoms appear. In torpedoed vessels, when the passengers were removed to rafts amid signs of disorder and carnage, and exposed to extreme hardship and privation, hysteria did not develop. Only when rescued did the passengers develop such a condition. Some illuminating observations were made. Soldiers were more frequently affected than officers. Crack regiments showed fewer cases than others. Men with severe wounds never developed it. Prisoners of war did not experience it. Here, as in civil life, it was seen that the disease was a disorder of conduct. It occurred among those men who were dissatisfied and fearful and who could not be separated from actual warfare by legitimate causes, as capture or injury.

A state of dissatisfaction leads to the illicit motive back of hysteria in civil life; it may be due to unrequited love, marital incompatibility, inadequacy of effort to support a family, fear of discovery of crime, etc., etc. In warfare it was due to fear of death and desire to escape. Following injury it may be due to several causes: (1) fear of being severely injured, unable to resume occupation and support of family with ensuing desire for pension; (2) resentment and desire for compensation, and rarely for causes not associated with either of these two, such as would have produced hysteria had any other "accident" than injury, occurred.

Is it meant by this that these patients are faking, putting this on, that they hypothecate their illness? It is not. They suffer just as much as if they were disabled from organic causes. Is the condition imagined? It is not. No more than the hypnotized person imagines that he can feel no pain. He feels no pain. The symptoms are real enough, but they occur only because of suggestion, not because of injury or shock. Usually the patient is injured or is in an accident, he experiences some pain or slight disability, he is fearful lest it be serious, he becomes introspective, attentive to himself, sensations which formerly he

would dismiss are now indicative of serious ailment. His friends ask him innumerable questions with entailing suggestions. An enforced period of idleness occurs. He is examined by physicians, who, by injudicious questions suggest new symptoms. He is fearful lest he be unable to resume his occupation and support his family. Here in short is a well prepared field for the development of severe signs of hysteria. He seeks compensation and legal advice and forthwith a hysteria develops. It does not occur immediately after accident, it occurs following a latent period during which time suggestion has had an opportunity to act.

### Not Malingering

It would appear that this description would fit a malingerer. Are these conditions the same? Emphatically not. A malingerer is a willful imitator of disease for the purpose of gain. One may not be able, by means at our hands, to say that this man is a malingerer or is a sufferer from hysteria. This inability is our own fault and not the man's. It would be the grossest of injustice to many patriotic and consciously willing soldiers to compare those who developed hysteria to one of the cases I observed in France in a man nicknamed "Bosco." He imitated a case of painful bent back and exclaimed to those about him, "Follow Bosco and go to Hoboken—follow 'Black Jack' and go to Hell." Although back of both conditions is an illicit motive, the hysterical patient is not aware of it. Of course, exaggeration and prolongation of symptoms may occur along with hysteria.

Frequently a malingerer may readily be detected and the condition at times easily differentiated from hysteria.

What relation does compensation bear to hysteria? It has already been said that desire for compensation induced either by wish for pension to assist in livelihood or by vengeful spirit, may provoke, engender or prolong a hysteria. How do we know this to be true? German statistics show that in spite of medical and surgical methods progressively improving, the duration of incapacity in some ailments and in accidents is greater than it was in pre-insurance days. Before the Netherlands adopted insurance, the German working man took much longer to recover than one injured in the same way in Holland. When, however, the Netherlands adopted an accident insurance, the duration of the illness suddenly in-

creased. In Denmark it is the custom to pay insured working men, lump sum settlements at a very early stage of their incapacity and 93.6 per cent recover from what is known as traumatic neurasthenia. In Germany, however, where the injured is entitled to a pension, only 9.3 per cent recover from the same disease. The introduction of the accident law in England in 1907 saw a marked increase in the number of accident cases. In France accident cases have increased by one-fifth and the duration of temporary disability is decidedly longer than before the operation of the law.

Some illuminating observations relating to these considerations may be mentioned. Five or six months after the Messina earthquake there was not a single person suffering from a neurosis caused by the earthquake. No source of compensation was available. When, some years ago, railroad employees were not compensated for injury, they were eager to return to work following an accident and it was the passenger who was afflicted with a traumatic neurosis. The availability of compensation, however, has caused the employee to develop such states as well. It is a common observation among social workers dealing with the poor, that if following illness, prolonged pension is carried out and return to work not encouraged or enforced, the individual becomes a chronic invalid and a ward of the charities. It has been found that in a certain group of people investigated, some 75 per cent of pauperism resulted from illness and this state was fostered by constant assistance without intelligent direction of rehabilitation by labor. At first assistance is abhorred, avoided, reluctantly received, then the morale weakens and assistance is sought, next it is expected and finally demanded.

It is the opinion of contemporary neurologists that were it not for possibility of compensation the traumatic neuroses would practically not exist.

Litigation holds out promise of reward and fosters the neuroses. Prolonged litigation prolongs the duration of a neurosis and prolonged forms of compensation work to the same end. Litigation is productive of ill effects through other causes. The presence of a patient before a board or court while his case is being discussed awakens a sense of resentment or distrust. A feeling that the corporation through its expert is trying "to do him." He develops the conviction that he is very seriously and permanently injured through the

histrionic efforts of his counsel and statements of ignorant witnesses. He has suggested to him new symptoms and promptly develops them. Some responsibility therefore rests upon our legal system for the production of these neuroses. It was held by the Fourth Chamber of the Tribunal in France in a certain case, that the incapacity with which the workman seemed to be affected resulted not from the accident, but from the erroneous opinion which the man formed of the rights to which he was entitled by persuading himself that an income was necessarily due him. For this reason compensation was refused. What is the result following a settlement of the case? Although it is claimed by some that settlement always cures a traumatic hysteria, I believe that there are occasionally exceptions to this rule. At times a traumatic hysteria may persist many months or years following such a settlement. This is rare and is always due to such difficulties as would have produced the hysteria had the accident not occurred. Such difficulties may be social maladaptations or deep rooted fears. If judiciously treated these cases may be relatively rapidly cured.

If a case of traumatic hysteria is to receive compensation, some idea of actual disability is necessary. A traumatic hysteria is curable. It does not produce any permanent disability. The severity of the injury has no relation to the type of severity of the hysteria. Severe symptoms have no relation to the duration of the disease nor are they an indication of a lasting disability. A paralysis of all four extremities may be cured in ten minutes, a slight spasm of the eyelids may last a long time. Harrowing experiences and extremes of horror or fright bear no relation to the severity of the illness. A complete paralysis may follow a slight sprain from stumbling and a Messina earthquake produce merely the winking of an eyelid. Whatever the symptoms, a neurosis is a neurosis and one case can be cured as rapidly as the other. However differing in detail, all accidents produce the same type of disability if it produces a hysteria.

Now to the milk in the coconut. Obviously, if compensation is one of the causes, it must either be dispensed with or it must be given in an innocuous form. As an indication of this mention may be made of the conclusion reached at a joint meeting of the Neurological Society of Paris and the Chiefs of Military Neurological

and Psychiatric Centers. It was voted that for hysteria neither dismissal from service nor gratuities were to be given. It has already been shown that early lump sum settlement tends practically to eliminate the long duration of these conditions. If existing laws are such as prevent such a settlement, refuge may be taken in arrangements between counsels for apparently such a settlement in the ignorance of the patient. Unfortunately, owing to the frailties of human nature, this is frequently unsuccessful. Prolonged litigation must be discouraged. After all the important thing is to get the patient well. A corporation lawyer remarked to me relative to this statement, "Perhaps from the medical standpoint, but not from mine." He was decidedly wrong. As soon as it is recognized that immediate final settlement cures a hysteria, it will be found that the amount of expense, otherwise prolonged, will be reduced. The quicker the patient recovers, whatever the initial cost, the less, in my opinion, will be the expense. Certainly an early and final settlement is the only just procedure for such a case. In addition to this several essential features in the handling of such a case stand out; an early and correct diagnosis by competent observers, avoidance of careless examinations and ignorant diagnoses, a quick return to some form of work, and avoidance of prolonged litigation and its ensuing chances for suggestions and fixation, particularly when the patient is an observer of the trial of his case.

### Perils of Daily Life Increasing

Recent figures sent out broadcast by the Census Department serve to indicate that 9,000 persons were killed last year by motor vehicles in the death registration area. The death rate last year from motor vehicle accidents was highest in California, Connecticut, New York and Washington. The highest death rate from this cause among cities was in Youngstown, Ohio, with Memphis a close second. Other reports indicate that more people are killed in the United States by accidental falls than are killed by automobiles. The staircase, though not as deadly as the motor, nevertheless numbers its victims by the thousands. Treacherous scaffoldings and defective sidewalks accounts for 10,323 deaths during the past year. Attention should be fixed upon these remediable causes in the effort to lessen accidents.

## Safety Congress Officials

THE Executive Committee of the National Safety Council at its first meeting following the Tenth Annual Congress, elected W. H. Cameron, formerly secretary-treasurer of the Workmen's Compensation Bureau, New York City, as executive secretary. Mr. Cameron, who on November 1 assumed charge of the headquarters of the National Safety Council at Chicago returned to a position which he held from the creation of the Council in 1912 to 1919. The following vice-presidents were elected:

David S. Beyer, Liberty Mutual Insurance Company, Boston, Vice-President for service to members.

B. F. Tillson, New Jersey Zinc Company, Franklin, N. J., Vice-President for industrial safety.

F. A. Davidson, Dwight P. Robinson Company, New York City, Vice-President for sectional activities.

C. B. Scott, Bureau of Safety, Chicago, Vice-President for local council.

David Van Schaack, Aetna Life Insurance Company, Hartford, Conn.;

W. H. Cameron, the newly elected executive secretary of the National Safety Council.

Vice-President for public safety.

W. E. Worth, Chicago Safety Council, Secretary and Treasurer.

resolution. He expressed regret at the absence of the United States from the conference, and hoped that America as one of the greatest consumers of East Indian wool, would participate in the proposed investigation. The voting on the resolution was deferred.

The Committee on white lead unanimously adopted the following resolution referring to lead poisoning, passed by the medical sub-committee: That medical science has been able for a long time to diagnose satisfactorily typical and severe cases of saturnism, acute or chronic lead poisoning. Modern methods of diagnosis in the hands of specially trained men enable them: (1) to recognize saturnism in the majority of doubtful cases; (2) to exclude cases of wrongly alleged saturnism; and (3) to recognize lead absorption and lead poisoning at an earlier stage than heretofore.

### Tuberculosis Among Grinders

The occupational hazards as related to the trade of grinders constitutes the subject of a study reported by W. Herbert Drury, M.D., in *Public Health Reports* of February 4, 1921. Intensive study was made dealing with the mortality from tuberculosis in a large factory in the state of Connecticut devoted to the manufacture of axes and other edged tools. The study developed the fact that these workers are subject to a very high death rate from pulmonary tuberculosis. The excess death rate among this group of "polishers and grinders" indicates that seventy-eight men have died during the past two decades as a result of industrial tuberculosis in these particular grinding shops. The maximum number of deaths from tuberculosis occurred at the age of forty-five years instead of twenty-five years as among the other operatives in the mill. This particular age incidence and the enormous excess death rate for the "polishers and grinders" being closely associated with the environmental condition of the industry. Although the problem is complicated by the fact that the grinders also represent a foreign group of low social status and intemperate habits, it is held by the Report that the dust produced in wet grinding is largely responsible for the enormous incidence of tuberculosis found in this industrial establishment.

## General Labor Congress

BY OUR LONDON CORRESPONDENT

TWO very important public health problems cropped up at the General Labor Congress held recently in Geneva—the use of white lead in paint and the question of anthrax. With regard to anthrax, Professor Armstrong, Australian employer's delegate, moved the following resolution: That the Committee consider that the question of the universal and compulsory disinfection of wool and hair infected with anthrax in its economic and humanitarian aspects to justify the establishment of an in-has not yet been sufficiently studied to justify the establishment of an international convention.

That the Committee should request the governing body of the International Labor office to appoint an advisory committee to which the governments of France, Great Britain, and Germany, as representing the users of the material, and Australia, India and South Africa representing the producers, should be invited to nominate representatives, and that this committee should be instructed to examine the question in all its bearings and present its report to the governing body in time for consideration for the conference of 1923.

That, in the meantime, the proposal of an international convention be postponed, that the Committee consider that the chairman of the proposed advisory committee should be nominated by the British government and that the inquiry should be at first mainly by correspondence but that when meetings of the committee become necessary they may be summoned by the chairman in London; and, further, that the cooperation of a representative from the United States should be invited.

The resolution finally states, that, while accepting disinfection as the only effective means at present available for protecting the workers against infection from certain classes of material, the committee regards the eradication of the disease among animals as the ultimate solution of the problem, and is accordingly of the opinion that the advisory committee referred to in the foregoing resolution should be further instructed to make full and careful inquiries respecting the most practical and effective methods for preventing infection.

Mr. R. Whitworth of the British Employers' delegation supported the

### Bibliography on Stammering

The September, 1921, issue of the *Laryngoscope*, XXXI, No. 9, contains a bibliography on stammering from 1911 to 1920, inclusive.

# Output and Hours of Labor

THE question of hourly, daily, and monthly output has been the subject of conjecture but of comparatively little objective analysis. Dr. H. M. Vernon in his recent book on "Industrial Fatigue and Efficiency" devotes a large part of his attention to the problems therein involved, bringing together and correlating statistical data and experience heretofore scattered and unavailable to many. He is primarily concerned with the relation of output to fatigue and efficiency.

It is found almost invariably that when some industrial process involving a muscular act is performed by a fresh and healthy individual that the efficiency of the performance gradually increases. In other words, it takes time to tune up the human mechanism to a satisfactory standard. Efficiency in these situations is attainable only with practice. This Vernon calls "practice efficiency." Simple muscular acts frequently repeated may reach a maximum in minutes or seconds, while with complex and coordinated muscular movements it may take hours or weeks to attain the result desired. On the other hand, fatigue tends to intervene and counteract the improvement of efficiency from practice. In some instances, the fatigue processes may never be sufficient to overpower practice efficiency and the output may rise steadily throughout each spell of work. Mental processes may influence the work in opposite directions, a feeling of monotony tending to depress the output, while the feeling that the work spell is nearing its end may tend to stimulate output temporarily. This is particularly evident in the end spurts which take place just before a holiday (Table I).

From this data, Vernon deduces a law that "experienced industrial workers unconsciously adopt habits of work which tend to the production of a maximum of output with the minimum of effort." In other words, as a matter of self-protection this

conscious or unconscious slowing up process is inevitable. In the United States we have not so far met with the conscious limitation of output

of an industry depends on the workers achieving a good output, not for a few hours or days, but for periods of weeks, months, and years. The conditions of production should not lead to a cumulative fatigue from which the worker does not recover

TABLE II.—VALUE OF GOODS PRODUCED BY EACH WORKER PER YEAR

	In 1886	In 1906	In 1912	Per cent change between 1886 and 1912
United Kingdom .....	£312	£275	£244	-22
United States .....	400	596	600	+50
Australia .....	333	462	542	+63
New Zealand .....	359	470	603	+40
Canada .....	341	...	472	+38

found in some countries. The above figures show the average value of goods produced by each worker per year. The variation may in part be due to depressions of trade, strikes, and other industrial or economic factors, but it seems very improbable that these reasons alone explain the situation, because of the steady increase of productivity in the United States, Australia, New Zealand, and Canada as opposed to the steady decrease in England (Table II).

with his week end of rest. If he does not so recover, his output will fall from the effects of fatigue until his experience shows him how far he may work within his physical power. When hours were reduced at the Zeiss Optical Works at Jena from nine to eight, the workers made a vigorous effort to increase their output, but the men overshot the mark and became fatigued, their output dropping from 19.5 per cent to 5.5 per cent. However, the output rose to 10.2 and

TABLE III

In the 74.5 hour week total output was.....	66.0 × 108 = 7128 (=100)
In the 63.5 hour week total output was.....	54.4 × 131 = 7126 (=100)
In the 55.3 hour week total output was.....	47.5 × 169 = 8028 (=113)
Among the men sizing fuse bodies the total output was:	
In the 66.7 hour week total output was.....	58.2 × 100 = 5820 (=100)
In the 60.2 hour week total output was.....	51.0 × 120 = 6120 (=105)
In the 55.5 hour week total output was.....	50.4 × 137 = 6905 (=119)

The question of output in relation to weekly hours, the reduction of the twelve hour day to ten hours, then to eight, and of 60, 55, 48, and 44 hours

12.9 per cent, where it remained. The output of a large number of women (100) was studied for ninety-three weeks (Table III).

TABLE IV.—OUTPUT OF BITUMINOUS COAL, ILLINOIS

	Average days worked per year	Average output in short tons	Percentage of coal cut by machine
1894 } 10-hour day.....	183 } 184	2.5 } 2.7	?
1895 } .....	182 } .....	2.6 } .....	?
1896 } .....	186 } .....	3.0 } .....	19.6
1897 } .....	186 } .....	3.4 } .....	19.7
1898 } .....	175 } .....	3.2 } .....	18.4

1900 } .....	214 } .....	2.1 } .....	19.7

of work per week is of the greatest importance to both employers and employees. How can the total output be increased by shortening the hours of work. The successful maintenance

In many industries in the United States the hours of work are entirely too long. Reductions in hours of work vary in their effects in the different industries according as that industry is dependent chiefly upon human labor or upon machinery. Vernon quotes a table concerning the output of bituminous coal miners in Illinois (Table IV).

The diminution of absenteeism and the increased output is too evident for argument, but 184 or 198 days' work out of 365 per year is well worthy of comment.

## Recent Compensation Decisions

THE Supreme Court of Illinois, June 22, 1921, in a proceeding under the Workmen's Compensation Act, held the evidence insufficient to show that an employee's condition was caused by lead poisoning rather than by infection from conditions having no connection with the employment.

The St. Louis Smelting & Refining Company operated a lead smelting furnace at which Joe Benno began work February 22, 1919, as a feeder, helper, and charge wheeler. "On April 19, 1919, while tending a furnace, he was affected by the smoke and gas of the furnace, and became dizzy and vomited. He lay down for a time and then walked home with some assistance from a fellow workman. He had pain in his stomach and in the calf of his right leg, and made application to the Industrial Commission for compensation, alleging that his physical condition resulted from an accident arising out of and in the course of his employment and that the injury to his leg was permanent."

The medical testimony will not be given in full. Dr. Harrison, the company doctor, was not at home. Dr. Armbruster was called and treated him until he went to the Barnes Hospital in St. Louis, October 2, 1919. Dr. Harrison saw him seven or eight days after he became sick. Dr. Eyerman of the Barnes Hospital examined Benno June 9, 1919, saying he had a bluish black line on the gum margin, and he gave him the usual treatment for the elimination of lead; that he had sciatic neuritis which could come from any local infection and could also come from lead; that he also had carious teeth, "and the witness then rendered an opinion that he was suffering from lead poisoning."

On cross-examination Dr. Eyerman said "that the improvement of Benno was not as rapid as it should have been, and that he might have been suffering from a focal infection, which is pus infection anywhere; that he was suffering from pyorrhea which was sufficient to cause the condition of the sciatic nerve; that sciatica might be caused by pyorrhea or lead poisoning; that he did not think that he had made the statement in direct examination that the sciatica was caused by plumbism; that in his opinion the plumbism had a very minor rôle in the causation of Benno's disability; that lead poisoning

might produce the symptoms described by Benno or might not, and the fact that the sciatica did not respond to the treatment for plumbism impelled him to doubt that plumbism might be a contributing cause of the sciatica."

Dr. Armbruster testified that he treated Benno for erysipelas, "and that this condition could not have been caused either in whole or in part by any lead poisoning or the breathing of gas nor be attributed to lead."

Dr. Harrison, the company doctor, testified that he had made a special study of lead poisoning, that he last examined Benno two days before he quit work, that he was then suffering from pyorrhea, that he had no blue line on the gum, and was not suffering from plumbism.

In the opinion of the court, "Considering the other testimony of Dr. Eyerman, there was nothing more than speculation or conjecture that the condition of Benno might have arisen from lead poisoning or from infection from conditions proved and not disputed.

"There was no evidence sufficient to sustain the award, and therefore the judgment of the circuit court is reversed, and the cause remanded."—*St. Louis Smelting & Refining Company v. Industrial Commission*, 131 N. E. 617.

IN A proceeding under the Workmen's Compensation Act to recover for the death of a servant, where injury received in the accident in question was an epigastric hernia, and when the physician operated the deceased servant employed him independently to operate for an inguinal hernia of long standing under the same anesthetic, and death resulted from the post-operative surgical shock, the Supreme Judicial Court of Maine, July 8, 1921, held that it was left to uncertainty and conjecture whether the servant would have died from the shock of the epigastric hernia. The court held that compensation could not be recovered.

"The inguinal hernia clearly was not affected by the accident. The operation on it was entirely independent of the ventral operation and done at the express request of the deceased, and was not necessary at that time. The accident only required the ventral operation, and even if the post-surgical shock of the ventral operation, together with the post-sur-

gical shock of the inguinal operation, did not contribute to his death, still the accident cannot be said to have contributed to his death, because the inguinal operation was not required by reason of the injury received by the accident, but was the independent act of the deceased, and without which it is not certain his death would have occurred.

"But if it was certain that he would have survived the ventral operation, then certainly death was not the result of the accident, because he voluntarily ordered an independent operation without which he would have lived; and, if the post-surgical shock of both operations did contribute to the death, it was not due to the accident, but entirely to his own voluntary act."—*Dulac v. Proctor & Bowie Co.*, 114 A. 293.

THE Supreme Court of Michigan, July 19, 1921, has stated that where the testimony is susceptible of the inferences drawn therefrom by the Industrial Accident Board, its conclusion is final, and the Supreme Court has no right to interfere.

The evidence showed that an employee was directed to go on a gondola car and was seen on it. A few minutes later he was found in a half-reclining position at the foot of the ladder leading to the top of the car. He complained of being hurt, and soon after died from acute dilatation of the heart, which, in the opinion of physicians, could be and usually was produced by a fall, over-exertion, or jumping. In the opinion of the court, the conclusion of the Industrial Board that he either jumped or fell from the car and that the shock caused acute dilatation of the heart was warranted.—*Shaw v. Packard Motor Car Company*, 183 N. W. 767.

THE Supreme Court of New Jersey, July 7, 1921, states that where a workman receives a personal injury from an accident arising out of and in the course of his employment, and a disease ensues, which, but for the accident, would not have ensued, and which disease causes his death, a finding that death was in fact the result of the injury and was within the meaning of the Workmen's Compensation Act is justified even though it is not the natural result of the injury.

The deceased was 72 years old, employed as a porter by the Regina Company. He was injured at his work February 6, 1921. "He was

caught between the door and the casing of the elevator and pinned there, with one leg within the elevator and the other on the outside, and remained in that position from five to eight minutes. It was necessary to pry the door away to release him. It was impossible to get an ambulance because of heavy snowfall. He was taken home within an hour in a sleigh. . . . The medical testimony as to the cause of the death was in conflict. The company insists that the cause of death was diabetes, or influenza, or both. But the physician called by the petitioner testified in effect that the accident was a factor in producing death."—*Geizel v. Regina Company*, 114 A. 328.

**A** DEPARTMENT store employee, while pulling out a large drawer, felt a snap in her chest and fell fainting, the drawer falling on her chest. After working for seven months thereafter she was operated on for cancer of the breast and her physician testified that neither he nor anyone knew whether a direct trauma would be necessary to produce such condition, but that "cancer may follow an injury." The Supreme Court of New York, Appellate Division, July 7, 1921, held that the evidence was insufficient to show that the cancer was a result "naturally and unavoidably" from an accidental injury within the meaning of the Workmen's Compensation law.—*Schapiro v. Wanamaker*, 189 N. Y. S. 313.

**T**HE Appellate Court of Indiana, June 30, 1921, held that the injury to a workman need not be the sole cause of his death, in order to entitle his dependents to compensation. It is sufficient if it is a concurring cause. The court sustained a finding by the Industrial Board that the cause of the death was the injuries sustained in an explosion in a local mine while the deceased was engaged in firing shots therein, and not to a mechanical obstruction of the bowels, as claimed by the employer.—*Miami Coal Company v. Lucc*, 131 N. E. 824.

**T**HE Supreme Court of Illinois, June 22, 1921, in proceedings under the Workmen's Compensation Act, held that the evidence that an employee who had a cerebral hemorrhage a few minutes after a fellow employee had threatened to strike him with a stick, with expert testimony that the hemorrhage might have been

caused by the excitement produced by the altercation or by another cause, or might even have occurred while the employee was in bed, does not show that the employee received an accidental injury arising out of his employment.

It was further stated that an employer cannot be liable under the Workmen's Compensation Act on a choice between two views equally compatible with the evidence, but such liability must be based on facts established by evidence fairly tending to prove them.

The facts in the case are stated: Fox was a yard foreman, Scanlan a teamster who went to the yard of the Ideal Fuel Company for a load of coal. "When he had his wagon partly loaded, Fox went to him and told him that he was loading the wrong coal and would have to unload it. Fox testified that Scanlan became angry, abused him, and threatened to strike him with a 'thick, strong board.' No blow was struck and no attempt made by either of the men to strike the other. A few minutes after the quarrel Fox started to fall, and a teamster who was standing near caught him and laid him down. The doctor testified that Fox had hemorrhage of the brain and a paralytic stroke. Fox was at the hospital eleven weeks and then returned home. He has never been able to work since February 4." The arbitrator made an award which, on review, was affirmed by the Industrial Commission.

In the testimony before the court the attending physician showed that the paralysis "was due to blood clot in the brain; that that condition could be produced by a 'fright or fracas,' but the doctor was unable to determine whether it was caused by the difficulty between the men. He testified a clot in the brain may come from a variety of causes. It may come while a man is asleep or after eating heartily. The doctor testified that where a man falls following a threat to strike him, the blood clot might be due to the excitement or the fall or many different causes; that it would be impossible to determine the cause of the hemorrhage, but from what he had heard of the quarrel he would judge that was the exciting cause. It is a matter of conjecture from the evidence, but he would not attempt to be positive."

In the opinion of the Court, proof that fear or excitement might have caused the blood clot is not sufficient, and because the proof also showed that it might result from other causes or occur at any time, it is not a rea-

sonable basis for liability. The judgment of the circuit court was reversed and the award set aside.—*Ideal Fuel Company v. Industrial Commission*, 131 N. E. 649.

## Occupation is Reported as Furthering Treatment

Physicians in charge of tuberculosis sanatoriums are often discouraged by the failure of a large portion of their patients to remain under treatment a sufficiently long period. Many such patients, disregarding the advice of their physicians, leave within a month of their admission. A recent report issued by the United States Public Health Service demonstrates conclusively the value in this connection of occupational therapy as an adjunct of treatment. As carried out by the experienced reconstruction aides of the United States Public Health Service, occupational therapy, consisting of mental work and manual handicraft for curative and diversional purposes, promises much in the medical care and treatment of discharged and disabled soldiers cared for in Government tuberculosis sanatoriums.

"Occupational therapy," said Doctor Lavinder, who is in charge of the United States Hospital for the care of disabled soldiers, "is one of the latest developments in the modern care of patients. It is applicable to all kinds of conditions and is given both for direct, curative action, for the improvement of function of muscles and joints, as well as for the marked effect of stabilizing the patient by increasing the morale. Our results with it have been excellent. Occupational therapy is not vocational training. In the hospitals of the United States Public Health Service occupational therapy is given to bed patients and those who are convalescent. When the patients have completely convalesced this form of therapy is succeeded by vocational training."

According to this report, out of 392 patients admitted to one sanatorium, 263 took occupational therapy and 129 did not. Of the former, only two patients left the hospital against the advice of physicians in charge. On the other hand, of the 129 who did not take occupational therapy, 83 either deserted or left the hospital against the advice of the physicians in charge. This is less than 1 per cent among the former, as against 65 per cent among the latter class of patients.

The Public Health Service operates the largest unit now engaged in occupational therapy and physiotherapy.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## The James Whitcomb Riley Memorial Hospital

BY JANE M. KETCHAM, M.D., INDIANAPOLIS, IND.

THERE is nothing dramatic or startling in the statement that children's diseases are of inestimably greater concern than are those of adult life. It is not that the usually considered simple illness of whooping-cough can kill ten thousand children in the year 1916 in a civilized portion of the United States. It is not that measles can put whole communities out of business, but rather it is the fact that measles is the precursor of tuberculosis which makes it an exceedingly important factor in our economic life.

Children's diseases are always acute in their onset and their after effects are the deciding factor which makes that individual child an asset to his community or a care to the

state. This is not the slightest exaggeration. The other day a woman came into my office. She was expecting to be taken care of during the

Fig. 3. The piteous plea of helplessness in children awakens universal sympathy, but not always a wise response.

club feet, for instance. Any woman who looks at her new baby's feet must know if they are not properly formed. She may not know, however, that the time of election to straighten those feet and make it possible for her child to run and play as others do is when that baby is very small. Or another mother may not know that the time to begin treatment for glandular deficiencies is as soon as the baby is born and not after the child has grown to man's estate and is a hopeless idiot.

The State of Indiana, aided by a number of representative citizens, is planning to erect a hospital which will take care of children's troubles exclusively and will undoubtedly be a great factor in the state for the

most major situation which ever faces any woman and she had been cruelly prepared for it. As a baby she was as healthy as any fond parent could wish. When she was seven years old she went through a prolonged attack of typhoid fever. In those days sufficient care was not given to the convalescence from disease; this little girl was allowed to get up too early and her poor little back just crumpled up under the strain. Her crippled spine was the result of the sheerest neglect, mostly the result of ignorance. But that woman, with all a woman's natural warm desire for children of her own, was facing what was for her an almost impossible condition.

### Time the Essence of the Matter

Every year in every state in the Union, millions of dollars are spent on the care of the insane and the criminal, almost two-thirds of which would have been rendered unnecessary by a much slighter expenditure on the conditions of infancy. Take

Fig. 1. What kind of a future could be predicted for this child if Science and Humanitarianism did not come to his aid?

Fig. 2. In this picture the same child in Figure 1 is shown well on the way to recovery. His whole outlook is changed.

Fig. 4. The proof of what adequate care will do for the child, even against the greatest odds, is shown in this result, accomplished for the child shown in Figure 3.

early prevention of those distressing conditions which make man's estate so intolerable. The hospital is to be in memory of Indiana's favorite son and will be named the James Whitcomb Riley Memorial Hospital. An executive committee of ten members, five from the Board of Trustees of Indiana University and five from the James Whitcomb Riley Memorial Association, will be in charge of the undertaking, but the hospital will be directly under the control of Indiana University, which will insure its perpetuity. The hospital will be a gift in fee simple to the state. Friends of the hospital who will give towards its establishment and maintenance will be assured that what they give will be well taken care of and prudently administered. The new building will face the Robert W. Long Hospital, which is the teaching hospital of the Indiana University School of Medicine, and there will be a parkway on the other side across which the Indianapolis City Hospital and the Burdsall unit may be seen. The grounds will be extensive and will insure plenty of fresh air and play space for little convalescents.

The law under which the hospital will be administered, provides that all of the children of the state of Indiana who need medical or surgical attention, may be admitted without cost to themselves, as rapidly as facilities will permit. Parents, guardians or anyone interested in a child needing such attention may present his case before the circuit judge of

his county, who has the power to place the child, and the hospital must admit the child as soon as it is possible to give it proper attention. If the parents are able to pay, they will probably wish to do so, but this is not compulsory. The state will provide funds for equipment and for operation of the institution, and it is planned to have 200 beds.

The plan of the Riley Hospital has been modeled after the State University of Iowa Hospital for children. The architect's plans provide for a group of two-story buildings around a central administration building. There will be wide and open porches where little wheel chairs and cots may be pushed and there will be gymnasiums for all the children who may use them, but especially for the orthopedic cases. It is the plan to be able to treat hundreds of children, whereas now the Robert W. Long Hospital possesses absolutely the only facilities at the present time to care for all of the needy children of the state. There is room for 24 children in the Long Hospital, and there is a daily waiting list of at least 50 who are really in need of immediate attention. There is no question of the need for such an institution. Civilization marches forward on the feet of little children. The question is: Who is going to see that those little feet become straight and strong?

A campaign has been started in all the schools of the state so that the children may help on this memorial

Fig. 6. If irreparable damage is to be avoided, these little crooked bodies must have applied early the most skilled orthopedic service. Society owes to every one of its children a place in the sun.

Fig. 5. Treatment delayed in such a case as this condemns the child to permanent deformity. If we care for the future, we must save the children.

to the children's poet. Groups of children all over the state are doing their bit toward this end. One of the directors for the new hospital is the professor of oto-laryngology in the Long Hospital. Last year a teacher wrote to him that she had two boys in her school who were in imminent danger of permanently losing their hearing. Their names had been put on the waiting list and had been accepted at the Robert Long Hospital, but there was a long waiting list. This teacher appealed to have the children attended to immediately, as their need was very great. To make a long story short, the teacher paid the expenses of the children to Indianapolis from her private funds, the doctor took care of the children and they were returned to their school in good condition. When the word went out about the possibility of a new hospital, children of the school from which these two had come, delighted at the care their playmates had received, banded themselves together and gave a play for benefit of the James Whitcomb Riley Hospital.

At the present time there is a drive on among the school children to raise funds for the Riley Memorial. It is hoped not only to raise funds for the hospital but to instill a vein of civic pride in the children, so that each child in the state may say: "This is my hospital; I helped to build it."

The Riley Memorial will be a lasting tribute to the poet whose name is known all over the world as the children's poet.

# Open Air Dormitories at University of Arizona

## Arizona is Unique in Providing Outdoor Sleeping Quarters for all University Students

BY A. O. NEAL, REGISTRAR, THE UNIVERSITY OF ARIZONA, TUCSON, ARIZONA

THE University of Arizona is unique in many ways. It is the university of the youngest state. In percentage of growth in the past six years it has exceeded all the institutions of higher education except four.

With the increased registration it is presenting administrative problems which challenge the best thought of its executives.

Necessarily the housing of the increasing number of students is a vital problem, and in the dormitory arrangements a plan has been evolved which is unusual in that all students sleep on open air porches. The dormitories have all the usual provisions of the college halls. There are reading rooms, social rooms, and congenial quarters for guests. All dormitories have showers and toilets on each floor, and all rooms are heated by steam from a central heating plant.

### Administrative Problems

Each women's hall is in charge of a competent head who has supervision of the work, health, and social proprieties of the members of the group.

In each men's dormitory there is a suite for the head resident, who is a member of the faculty. The plan followed is to have a man and wife, and in this way a home atmosphere is maintained.

While these provisions are usual in many institutions, accommodations for sleeping are unusual if not unique—all students sleep on open porches. This applies to women students as well as to men students. Students are required to sleep outside their study rooms and, if unable to adjust themselves to the condition, must secure living quarters off the campus or in the infirmary.

In addition to these dormitories operated by the University, there are six fraternity houses and six sorority houses with similar outdoor sleeping arrangements.

### How It Came About

The climatic conditions at Tucson during the school term made it very easy to follow the advice of those who

*The way to resume is to resume. If open air living lifts men to higher levels of energy, then why forge shackles for ourselves by habits of indoor living universally conceded to be a gratuitous handicap?*

*In most schools instruction in the laws of bodily and mental health are far from adequate. Health practices are too often conspicuous by their absence or by their remoteness from present application.*

*But here we have the scientific mood as the basis for action. Sound bodies and wholesome outlook are fostered and make for that stability of persistence of effort which registers itself in progressive achievement.*

recommended outdoor sleeping quarters. The climate is mild, dry, and equable. The rainfall during the winter is very light, fogs are unknown, and cloudy days rare. The percentage of sunshine throughout the winter months is greater than that recorded at any other place in the United States. The total amount of rainfall for the year averages less than twelve inches, the greater part of which comes in July, August, and September. These advantages insure a wide range of outdoor recreation throughout the college year. The nights are clear and the night temperature will average thirty degrees less than the maximum daily temperature.

The first dormitory—North Hall, built in 1898—was provided with sleeping porches upstairs and down. Each of these porches was fitted with

Maricopa Hall ..	1920	Women	113	3	Yes	Yes	180,000
Cochise Hall ...	1920	Men	142	3	Yes	Yes	225,000

The first floor plan of Cochise Hall, men's dormitory. The sleeping porches accommodate four single beds each, connected with two study rooms

North Hall, women's dormitory. The exterior view of this building shows the provision of sleeping porches, upstairs and down

fifteen single beds. The porches are reached by passing through long corridors from the rooms to the porch. The exposure of these porches is to the north and east. Rolling canvas curtains were provided for protection in case of driving rains. For twenty-three years the plan has proved satisfactory.

East College, built in 1896, provided sleeping quarters for sixteen girls. Here the sleeping porches were at the rear of the house and provided with double decked beds. This arrangement was unsatisfactory and has been discontinued.

When South Hall was built in 1900 it provided no open air sleeping quarters. The rooms were small, twelve feet square, and were suitable for one person to use for both study and sleeping. As the number of students increased, it became necessary to provide additional sleeping quarters, and beds were placed entirely outside the building. This practice led to the provision of two large wings on the second floor. These were open on three sides and provided space for thirty-five single beds on each of the two screened porches. This plan has the disadvantage of having a large number of persons occupying the same porch. This lends itself to confusion or disturbance through the movements of so many occupants.

In Arizona Hall, built in 1912, a different plan is provided. Here the building is built on the "U" plan with all rooms outside rooms with a screened porch around the central court. Each room opens upon this porch, which serves as corridor and sleeping porch. Single beds just outside the door of each room provide sleeping quarters for the occupants of the room and make is unnecessary for them to

pass through long corridors or stairways going from room to bed, or *vice versa*. This plan is satisfactory and has many desirable features.

Maricopa Hall, a dormitory for women, was completed in 1920. It has three floors accommodating thirty-five girls each. The rooms accommodate two girls each and are all outside rooms. On each floor there are three sleeping porches, so that the number of beds on each porch is limited. The passageways from rooms to sleeping porches are heated so that in extreme weather there is no exposure. The porches are screened and curtains provided, which are used only in case of driving rain or wind-storm. The architects for Maricopa Hall were Messrs. Lescher and Kibby of Phoenix, Ariz.

Cochise Hall, just completed, is regarded as the last word in dormitory arrangement. In this building, which provided quarters for 110 men, study rooms are provided to accommodate two students each. These rooms are in suites of three, two study rooms and a sleeping porch situated between the two rooms. The sleeping porch is provided with four

single beds and this provides the outdoor sleeping porch. This has the advantage of having a sleeping porch directly connected with the rooms, and the number of occupants is limited to four. This minimizes opportunities for disturbance as well as providing greater privacy and is much more satisfactory. The architects for Cochise Hall were Messrs. Lyman and Place of Tucson, Ariz.

The experience of twenty years has led the administration of Arizona to the belief that this

Maricopa Hall, women's dormitory, showing arrangement of beds on sleeping porches, interior of central wing

Exterior view of Maricopa Hall, women's dormitory. A good view is given of opening for sleeping porches on three floors

Arizona Hall, men's dormitory. Interior view, showing arrangement of upper and lower sleeping porches, accommodating thirty beds on each floor. These porches extend around three sides of the patio and the upper and lower floors are seen in the background.

plan is thoroughly satisfactory. It affords rest and sleep in the open, the benefits of which are shown in the vitality and work of the students.

It is not unusual for students to make extraordinary gains in weight and endurance in remarkably short time and this is in part attributed to the dormitory plan. Few students are willing to return to indoor sleeping rooms after having had a semes-

ter's experience sleeping in the open air.

There are some features of the plan which are readily adaptable to localities where the climate is not so favorable as in Arizona. The plan of Maricopa Hall or of Cochise Hall is readily adapted to other situations and could be used in any climate where the plan of outdoor sleeping is endorsed.

## Launching a Penny Lunch Room

By HAZEL M. SHULTZ, CHICAGO

TO OPEN a Penny Lunch Room during the last months of climax prices, and the first months of "No work," and still to hope to have it pay even twenty-five per cent of its cost seemed only the visionary idea of the inexperienced. Nevertheless such a school lunch plan was launched at just such a bad time, from a business man's point of view, and it was hoped to make it something of a financial success even though its primary aims were far from financial. The children to whom the food was to be served needed quantity and quality; but, more than either of these, what they needed was education with regard to those foods which contribute to childish health and happiness. The zeal of those interested in conducting this Penny Lunch project prompted a desire to make of it something of a financial success only because by so doing other lunches in other schools could and would then be attempted.

The community in which the work was started was such that the most

effective method of teaching food values seemed to be that of demonstration, hence it was thought that a lunch room open to any one but established for children was a primary necessity.

The location was a bit unique in that it was less than a dozen short blocks from the magnificent capitol building of the state of Pennsylvania. In this community is a fair representation of almost any nationality; but the predominating races were Jews, Italians, Serbians, and Roumanians. Besides the foreigners there was a large colored population, and a few white American families were represented. Most of these people were far less poor in money than in education or ideals, for they had for the past several years been earning comparatively large wages.

As might be expected, there was much of vice to be found on these streets. The children were in some cases loved but badly cared for because of drunkenness or ignorance on the part of their parents; but in

most cases they were regarded only as a burden until the day when they were old enough to at least appear fourteen years of age and be granted a work certificate. As the result of such an attitude on the part of parents it was not unusual to inquire of a child as to his breakfast and be told that he had had none or that it consisted of a glass of beer and coffee, dirty candy purchased on the way to school, or perhaps sauer-kraut from a tin can set in the middle of the table and from which every one helped himself according to his desires. Such living meant, of course, that the school attendance was always irregular and that the children in attendance could not do standard grade work because of their undernourishment.

At the suggestion of the teachers in the neighborhood grade school a community house had been established next door through the cooperation of the Child Welfare Organization. It had functioned for a year or more, and was unusually fortunate in having as its social worker a young woman who had not only been trained for community work, but who was so genuinely interested in this particular neighborhood that no project was too great for her to attempt, if it ministered to the real welfare of the people. It is not strange that with a background of interest such as this

A typical group of Seventh Street children who were served by the Penny Lunch Room.

Bad habits, prejudice, ignorance—all were considered and all were routed in this group by the scheme of the penny lunch.

even the apparently impossible could be attempted.

### Soup, Soap, and Salvation

Some missions hang a sign over their doors "soup, soap, and salvation" and such a slogan would probably not have been out of place in this little enterprise. According to the general plan the children were first to be given nourishing food and then taught. They were to be given the right kind of food, plenty of it, trained to a certain degree of cleanliness when eating or handling foods, and, lastly, taught why these things were being done for them. Certainly a place of demonstration was essential and it was decided that it should be a "Penny Lunch" in an unused room of the grade school building.

This room the Board of Education granted and with it a few benches, old desks, and a small table. The Child Welfare Organization provided the remainder of the equipment with the exception of a fireless cooker which the children of the neighborhood bought with their pennies and nickels. The fireless cooker together with a two burner gas stove and the occasional use of a range oven at the community house next door supplied the stove need. For the comparatively small sum of twenty-eight dollars a most satisfactory steam table was made by a tinsmith. It consisted of

a galvanized tin box provided with a pet cock to drain away the water, and a gas jet beneath to keep the the water hot when in use. It had four holes for insets—the insets were extra kettles from the fireless cooker—and a little tin frame over the bottom to keep the insets up and prevent sticking and burning. This steam table was used not only to keep the prepared foods hot, but it was utilized to make cocoa, to warm buns, and to finish cereals and cornstarch puddings. Two tables and an exceedingly large cupboard, both of which had been used in a Red Cross sewing room, a set of aluminum serving dishes, such as were used during the war in cantonments, a few good kettles and knives, and many smaller utensils purchased in a ten cent store completed the simple equipment.

When on October 11, 1920, this business was, at last, ready to open its doors to the little patrons, it was found that no extensive advertising campaign would be necessary and that there were pennies a plenty. It was necessary only so to control the line that every child would have a chance to spend his pennies for the foods he wished. Older children went home for little brothers and sisters, some of whom could not ask in English for the foods.

The morning lunch would consist of a cup of milk and a bun or graham crackers, or cocoa instead of milk, or it might be a bowl of cereal with sugar and a cup of milk. Much of the time fruit, as prunes, apricots, stewed or baked apples, and occasionally stewed raisins were to be had. Each serving sold for one cent, and every child could choose according to his likes except that he was not permitted to select a lunch in which there was no milk. The best grade of milk was supplied and each penny portion was over five-eighths of a measuring cup full, allowing slightly more than one hundred calories to each serving. The cocoa was made of skimmed milk, for two reasons: first, because it could be bought for ten cents a gallon; and, second, it was desired that the children and community should learn the correct use of skimmed milk. They were to learn to use plenty of raw whole milk and to also take advantage of the low cost of skimmed milk in such cooked foods as were otherwise prepared with water. The number of servings which a child might have was governed by the number of his pennies, his appetite, or his size. Not every child came with enough pennies to buy a sufficient amount of food

for his height and weight, to say nothing of his appetite. Such cases were usually investigated by the teachers and money in proportion to the individual need was supplied by interested persons or organizations; but every child paid for his lunch at the time that he received it and each was a self-respecting and honorable little citizen.

### A Point of Honor

No one ever attempted to cheat in the lunch room, for such a thing was not well regarded; yet it was found that one little fellow who always came with an amazing amount of money was a member of a well organized group of boy thieves. Like the pirates of old, they buried their booty and dug it up according to the daily or weekly need. When questioned he revealed a startling attitude. He felt that this stealing was merely a business; but cheating on his lunches was a contemptible trick; "No good boy would do that," he declared.

To those who anticipate establishing a little lunch room, the question of labor is always a most important one. In this case the labor question was solved by almost perfect cooperation from everyone interested, and there were not a few people to be so classified. The social worker was the only person directly paid for work on this project, and she was paid to

It was not unusual among these children to find they had come to school with no breakfast other than beer or coffee, and sauerkraut with or without a crust of bread.

spend slightly more than a half day at this piece of work. Church and club women came on certain days assigned to them and assisted in the preparation and serving of the foods. A group of boys from the seventh and eighth grades formed a club and volunteered to wash the dishes and go for supplies. The teachers assisted by keeping in touch with the financial condition of the homes and indicating cases which were in need of outside aid. It is doubtful whether any volunteer group of women have been more faithful to a piece of work than were these club women. Out of ten, five came every week during the entire year, and two others missed but one week. Because of the volunteer help, the menus were very similar from week to week. The women arrived each day at ten o'clock, poured the milk, and arranged the crackers and buns, the cereals, cocoa, and fruits having been previously prepared. One woman seated herself at a card table on which was placed a small tin can cash register, and the other women assisted the children as they passed in line to get the foods they desired or should have. In a few cases true salesmanship was necessary in persuading a child to buy wisely. The woman at the cash register usually watched the pennies drop, and occasionally made change for a nickle or a dime.

The role of dishwasher became a lark to these boys because it was shared and self-imposed. These volunteer workers served the school year through.

Early in the year few children thought to wash their hands before coming in to eat; but, later, when a chart was hung on the wall and each child was encouraged to keep a record of his hand washing habits, a decided difference in complexion began to be revealed.

After the meal each child carried his dishes to the kitchen—a cloak room had been converted into a kitchen—where the boys stacked and washed them. Because of the fact that many of the children were orthodox Jews, soap could not be employed for dishwashing, hence it was necessary to find something that was not derived even in part from "pig" that would thoroughly cleanse the aluminum dishes used. Lysol proved to be most satisfactory, since it does not cause discoloration of aluminum which results from the free alkali of soap and, besides having antiseptic properties, it produces something of a suds. The dishes were all rinsed before washing, which practice helped in preserving the sudsy qualities of the lysol. With thorough rinsing after washing, no odor or taste can be detected on the dried dishes.

The matter of washing the dishes became a real pride with the boys, and, much to the surprise of all grown-ups concerned, they continued the "Dish Washing Club" until the end of the year. These boys also burned the garbage, and swept the floor each day. One chap was responsible for lighting the gas under the steam table each morning before the social worker arrived, which meant a saving of almost a half hour to her, since in this way the table was hot and ready for the making of cocoa, and to receive the cereal which was transferred from the fireless cooker to it.

The menus, as well as the equipping of the lunch room, certain of the plans for the daily routine work, and the financing of this project, were worked out in cooperation with a home economics extension service worker from the Pennsylvania State College. The menus were governed by several factors, chief among which were religious prejudices, perverted appetites, and the purchasing power of a penny, as well as the true nourishing qualities of the foods. There follow several typical menus. As much variation as possible was practised from week to week. The foods starred are the ones which, when sold for a penny, meant a money loss to the lunch room. At present wholesale prices almost none of these will mean a loss. The number of calories

Inanition attacks the tissues in the order of their importance, reacting less quickly on the motor organs than on those of nutrition. Inanition is particularly to be avoided in children, their development suffering from it. Even if followed by abundant nourishment, the normal development of the muscles is permanently affected.

indicated in parenthesis after each food was computed upon the basis of United States Bulletin No. 28 "Chemical Composition of American Food Materials," according to the recipes used and the size of portions given.

#### MENU No. 1

1 cup cream of pea soup (150).  
Baked potatoes.  
1 bun, baker's (90).  
 $\frac{5}{8}$  cup milk (100).  
1 cup cocoa (125).  
 $\frac{1}{3}$  cup apple tapioca custard (125).

#### MENU No. 2

Vegetable stew (250).  
Caramel cornstarch pudding,  $\frac{1}{2}$  cup (200).  
Buns, milk, cocoa, graham crackers (2 for one cent), were always to be had.

#### MENU No. 3

1 serving spoon of baked meat (125).  
1 cup creamed potatoes (125).  
Sugar bun (125).  
3 stewed prunes (100).

#### MENU No. 4

1 cup baked beans (250).  
 $\frac{1}{2}$  large baked apple (100).  
Occasionally sponge cake (100).  
\*

#### MENU No. 5

1 cup hard cooked eggs and potatoes creamed together (125).  
 $\frac{1}{2}$  cup apricot tapioca (150).

#### MENU No. 6

Cream of bean soup (150).  
Bran bread (200).  
 $\frac{1}{3}$  cup chocolate cornstarch pudding (125).  
Candy occasionally.

#### MENU No. 7

Baked macaroni and cheese (200).  
 $\frac{1}{2}$  cup stewed apples (75).  
Ginger bread (150) occasionally.\*

#### MENU No. 8

1 cup macaroni stew, prepared with meat stock and tomatoes (125).  
 $\frac{1}{2}$  cup custard bread pudding (125).

Once a month a local ice cream dealer allowed the lunch room one gallon of ice cream for each gallon paid for and in this way ice cream appeared in the menus.

That this lunch room met a need was evidenced by the fact that a second one was established some two or three months later, and this year a third one has been installed in a third grade building. The school report proved the lunch's value by showing

the highest increased percentage attendance on record, and a better grade of work done by those in attendance. The financial report showed that, aside from the salary of the social worker, this business had been more than 80 per cent self-

supporting during the entire period.

In an early issue of THE NATION'S HEALTH an article will give an outline of the plan of work and will describe the results of a demonstration nutrition class conducted in connection with this lunch room.

## Control of the Cardiac Diseases of Childhood

By JACOB SOBEL, M.D., ASSISTANT DIRECTOR, BUREAU OF CHILD HYGIENE, DEPARTMENT OF HEALTH, NEW YORK CITY

IN DECEMBER, 1920, Dr. Royal S. Copeland, commissioner of health, City of New York, appointed a committee consisting of the Director of the Bureau of Child Hygiene, Director of the Bureau of Preventable Diseases, and the Director of the Bureau of Hospitals, to study and report upon methods for the control of cardiac diseases. At the time of this study, as Acting Director, I was delegated to formulate that part of the report which related to cardiac diseases in childhood. The second part of the report, dealing with the subject from early adolescence to adult life and old age, was assigned to Louis I. Harris, M.D., Director of the Bureau of Preventable Diseases. The following statements are presented as submitted in my report to the Commissioner of Health.

The members of the Committee realize the need and importance of the prevention, early detection, and prompt and proper care and relief of all cardiac diseases and abnormalities; the value of educational propaganda among physicians, nurses, social workers, teachers, parents and children; the growing disease incidence and mortality from these diseases in middle and later life; the possibilities of preventive measures; and the important rôle the Department of Health can play in this program.

### Cardiac Efficiency

In view of the loose use of the term "cardiac" or "heart disease" by physicians, nurses, and health departments in general, the many and varied classifications adopted by workers in this field, the diverse interpretation and importance placed upon different physical signs and symptoms, and the insistence by some specialists upon the use of elaborate instruments of precision for arriving at a correct diagnosis, the Committee feels, and so recommends, that the first and most important action to be taken in any community program for the study, prevention and

control of cardiac diseases should be the designation by the Commissioner of Health of a Committee of Pediatricists and Internists to agree upon and formulate practical, clinical, standard diagnostic criteria, and classifications of cardiac diseases, disturbances, and abnormalities.

The old conception of cardiac disease—the murmur conception—is now passé. To many the heart with a murmur, is of far less serious import than muscular disease of the heart or arterial disease of the cardiac arteries, often unassociated with a murmur. There is a great deal more to cardiac disease than murmurs—the capacity of the heart for work, the exercise tolerance, is now the determining element of importance. Furthermore, many signs and symptoms heretofore considered diagnostic of cardiac disease, as such, are no longer deemed of serious import. There is no doubt that many conditions in children and adults are erroneously termed cardiac disease. On the other hand, many serious cardiac diseases and conditions are overlooked or undiagnosed because of the conception in the minds of many physicians that a murmur is an essential and necessary feature. The entire subject is one that is now being studied by the best medical thought, and consideration and control of the subject, from the public health point of view, will be productive of the best result if we have as a basis, a classification of kind and degree to work upon, such as the standard classification herein recommended will afford.

This recommendation carries with it the suggestion that the State Commissioner of Health be requested to designate two members, with a view that the standardization be accepted by the state as well as by the city, and that the members of the present Committee be designated as ex-officio by the new Committee.

The Department of Health is naturally concerned primarily with the prevention of cardiac disease and with the institution of such measures,

through its various agencies, as will minimize the further extension of the process in those already affected. In any community program the subject of cardiac disease control must be considered and approached from two angles; first, cardiac disease in childhood, and second, cardiac disease in adult life.

### As Affecting Childhood

Congenital cardiac disease is beyond public health control. The most that can be done is to educate and advise parents as to the greater susceptibility of such children to infection and intercurrent conditions and to emphasize the importance of extraordinary care in their daily life. Regulation of daily routine, of exercise, avoidance of undue exposure, and vocational guidance are the limits of possibilities.

Under six years of age, acquired cardiac disease is relatively infrequent. At this age however, and particularly during the pre-school age—from two to six years—many conditions exist which, if disregarded or neglected, act as predisposing factors for the establishment of cardiac disease in later childhood—the school age—six to sixteen years. The Committee therefore feels that there is opportunity for public health education during this formative and plastic period of childhood along the following lines:

(1) The need of more frequent physical examinations during the pre-school age period, and the correction of remediable physical defects. Parents should be urged to have these children examined by private physicians, hospitals, clinics, dispensaries, in a special "pre-school age clinic"—a number of which have already been established in New York City—or at the baby health stations of the Department of Health and other agencies.

(2) Removal of abnormal and diseased tonsils as a potential source of rheumatism, and the most frequent cause of cardiac disease in children.

(3) Greater attention to nasal hygiene—teaching these children, wherever possible, the proper method of blowing the nose and using the handkerchief. Removal of adenoids and correction of other defects of nasal breathing.

(4) Maintenance of a proper standard of nutrition, through education of the parents in the proper purchase, selection, preparation and care of food with regard to the needs of growing children; regular periods of feeding; establishment of good health habits—mastication, sleep, ventilation, exercise, rest, fresh air, avoidance of tea and coffee, etc.

(5) Emphasizing that recurrent tonsillitis and enlarged tonsils are often forerunners of rheumatism and cardiac disease.

(6) Education of the public as to the dangers of cardiac complications following the infectious diseases of childhood—the need of prevention, the importance of early and proper isolation of the affected person, the value of prolonged rest in bed during the course of the disease, and the advisability of very gradual return to daily routine and exercise after these diseases, and indeed after every febrile disease of whatever nature.

(7) Further education in oral hygiene during the pre-school age period—daily cleansing of the mouth and teeth, correction of dental caries and defects.

(8) Prevention of respiratory diseases in early childhood through publicity measures heretofore outlined; dangers of coughing, sneezing, spitting; contact with other members of the family; proper ventilation in the home; danger of mouthing toys and other articles; avoidance of wet feet, exposure, fatigue, etc. These should be emphasized especially in the case of families forced by necessity to live in basements which come perilously close to being cellars.

(9) Greater regard for so-called "growing pains" which are also potential signs or forerunners of rheumatism.

(10) Improvement of the emotional and temperamental stability of these young children through: (a) Education of the parents as to the importance of environment and home training. (b) Proper food, hygienic and living conditions, personal and home hygiene. (c) Modification of the kindergarten system. At present the transition of the child from home to school is too sudden. He is often bewildered, with the result that he frets and worries and becomes discontented or unhappy or worse. He should be

taken more gradually into his new environment. The kindergarten registration at the present time is too high for one teacher to supervise, and the kindergarten should be made to conform more nearly to the Froebel idea.

(11) There should be more open-air play, and certainly more open windows in the classrooms than is the case at present. Improper kindergarten conditions predispose to fatigue, depression, emotional instability, lack of resistance and malnutrition. If children must be sent to school at an age as early as five or six years, it seems to the Committee to be a community responsibility that they should be placed under the most favorable conditions possible.

### The Heart of the School Child

At six years of age the child goes to school. In the opinion of the Committee, it would be better if eight years were established as the age of admission to school instead of the present age of seven as required by the Compulsory Education Law. The child is now transplanted from home to school environment, from the individual care of the mother to the divided care of the teacher. He comes in contact with many new faces, ideas, surroundings, and people. He is subjected to greater discipline and does not get "what he wants when he wants it." He has certain responsibilities of study and competition. He is "let loose" in a sense and becomes more active. In fact, in many instances, he is perpetual motion itself. Greater exposure, greater contact, greater activity, mean greater possibilities of strain, fatigue, and infection. Thus, cardiac disease is more common during the school age than during the pre-school age period.

The experience of the Bureau of Child Hygiene, based on many years of observation and study, indicates that.

(1) Approximately 2 per cent of the elementary school population is suffering from cardiac disease. The term "cardiac disease" as herein used is to be interpreted as indicating one or other form of chronic endocarditis, with murmur. This percentage might be found to be slightly higher were it possible to examine these children under more favorable conditions. Holt estimates that 2½ per cent of the child population of school age has cardiac disease. Examinations conducted by inspectors of the Bureau of Child Hygiene showed that in recent years, that the percentage of cardiac disease found among school

children of the elementary schools, was as follows:

1915	.....1.5%	1918	.....1.6%
1916	.....1.9%	1919	.....1.5%
1917	.....1.8%	1920	.....1.3%

(2) The percentage of cardiac disease in elementary school children based upon a study of 356,299 physical examinations at all ages—figures for 1909—shows a gradual increase from eight to fourteen years of age, slightly higher in girls than in boys. The percentage of cardiac diseases is somewhat higher among high school pupils than among those of the elementary schools. This gradual increase from eight to fourteen years of age may be accounted for by the following considerations:

(a) The existence of abnormal or diseased tonsils and adenoids, and failure of parents to have these foci of infection removed at any early age.

(b) The greater amount of dental decay and pulp infections found in children of the older age groups.

(c) The fact that children of the older age groups resort to more violent exercise with resultant greater exposure, and more frequent respiratory infections, especially influenza.

(d) The greater amount of improper and irregular feeding in the older children resulting in lowered vitality; also the ill effects of mal-nutrition which are carried over from the younger years—eight to ten—and which offer a point of least resistance. (e) Increase in the amount of chorea and nervous diseases found among boys and girls from eight to fourteen years of age, reaching its maximum at the fourteenth year.

(3) The 2 per cent estimation above mentioned corresponds closely to:

(a) The percentage found by private physicians in the case of physical examinations made in accordance with Section 200 of the Sanitary Code (1.9 per cent). (b) The examinations conducted by the Division of Institutions of the Department of Health (1.9 per cent). (c) Special examinations now being conducted by the Bureau of Child Hygiene of the Department in the Borough of Manhattan for admission to special classes conducted by Dr. Halsey (2.3 per cent). (d) A large series of examinations conducted several years ago by the Bureau of Child Hygiene in the Borough of Brooklyn, under the personal direction of the district medical supervisors (3 per cent). (e) A large number of examinations conducted by Dr. St. Lawrence in one of the public schools in Manhattan, in cooperation with the Bureau of Child Hygiene.

who reports slightly over 2 per cent.

(4) The causative factor of cardiac disease in children is predominantly rheumatism—acute infectious arthritis. It has been estimated that the majority of cases have this etiology in childhood. Rheumatism as herein used, is to be considered active or potential, the latter including chorea, recurrent tonsillitis, growing pains, joint pains, and muscular pains. Next in order come the infectious diseases of childhood—scarlet fever, diphtheria, whooping cough, measles; then decayed teeth; and, finally, the respiratory diseases—influenza and pneumonia in particular.

(5) If, in addition the chronic endocarditis with murmur, which forms the basis of our 2 per cent estimation already noted, we were to include other types of cardiac disease and abnormalities, not infrequently found in school children, such as hemic murmurs (now termed "insignificant cardiac murmurs"), neurocirculatory asthenia,—corresponding to the "disturbed action of the heart" found in soldiers—various irregularities, myocarditis, etc., the number and percentage of cases of cardiac disturbances among children of elementary school age would be increased.

### Preventive Measures

(1) All of the general measures outlined for the pre-school age period, apply with equal or even greater force to the period of school life.

(2) Further emphasis should be laid upon instructing parents as to the relation of the abnormal and diseased tonsils to rheumatism and cardiac disease and to secure removal of these predisposing factors. The relation of recurrent tonsillitis and other rheumatic manifestations to heart disease is so important that a circular used in the children's heart clinic at St. Luke's Hospital is herein incorporated as suggested copy to be used for general distribution by the field force of the Bureau of Child Hygiene.

### ST. LUKE'S HOSPITAL—CHILDREN'S HEART CLINIC

Heart disease in children almost always occurs as the result of acute rheumatism, St. Vitus Dance or chorea, growing pains in the joints, or repeated attacks of sore throat. Because of their relation to the heart, these conditions are most important and every effort should be made to cure them and prevent their recurrence. Much can be done in this direction and if successful the heart may be spared from disease.

Heart disease does not always make itself known and a serious condition may be present without giving symptoms. Therefore, occasional examinations are advisable. Usually, however, serious disease may be detected by shortness of breath, palpitation, and rapid beating of the heart.

To cure and prevent the recurrence of these rheumatic conditions and to properly care for

hearts already diseased, diligent and intelligent management over long periods of time is absolutely necessary. If your child suffers from any of these conditions, it should be examined at the heart clinic and, if advisable, enrolled in the special class. With your earnest cooperation the results may be measured in years of happy life, and, at times, in life itself.

(3) Continued and intensive medical inspection of school children for the early detection and quarantine of infectious diseases.

(4) Further propaganda to educate parents as to the dangers of decayed teeth as foci of general infections and of cardiac disease.

(5) Instruction in health and food habits—avoidance of tea, coffee, cigarettes, etc.

(6) Avoidance of strain, overexercise, fatigue, undue exposure, etc.

(7) The Director of the Bureau of Hospitals will forward periodically to the Director of the Bureau of Child Hygiene a list of names, showing ages, addresses, nature and severity of the infectious disease, and special indications for follow-up of all cases discharged from the departmental hospitals. Special attention will be given to these cases upon their return to school.

(8) Special attention, similar to the above, will be given to all cases of infectious disease returning to school from their homes after recovery.

(9) Greater selection by teachers, as regards school studies and home work of children handicapped by neurotic temperament. It seems to the Committee that less home work, in general, for school children, is advisable. Many children are pressed too hard and the curriculum overburdens them.

(10) Increase in the number of open-air classes in public schools. If this is impossible, open-window ventilation should be established in place of forced ventilation. A study made several years ago by the Director, Bureau of Child Hygiene, in cooperation with the State Ventilation Commission showed that: (a) Children in classrooms with closed windows and ventilated by mechanical methods were more subject to respiratory diseases severe enough to keep them from school attendance than were children who were in classrooms kept at the same or lower temperature and ventilated wholly by open windows. (b) Children in classrooms with closed windows and ventilated by mechanical methods were more subject to respiratory diseases not sufficiently severe to keep them from school attendance than were children who were in class rooms kept at the same or lower temperature and venti-

lated wholly by open windows.

(11) Shortening school sessions. It is recommended that school hours be only from nine-thirty o'clock to noon and from one-thirty to three o'clock. These hours would afford greater opportunity and time for proper breakfast and lunch, minimize hurry, excitement and bolting of food, indigestion and mal-nutrition—all predisposing factors to neurosis and cardiac disturbances.

(12) Parents should be urged to be present at the time their children are physically examined by the school medical inspectors. This would afford (a) an opportunity to notify parents directly of the defects found and the indications for treatment, and (b) the possibility of examining the child with chest exposed, with greater likelihood of accurate diagnosis. This procedure, while valuable for defects in general, is of special importance in the case of cardiac derangement.

### Occurrence in High School Age

*Fourteen to Seventeen Years:* In proportion to their number, cardiac disease appears to be slightly more frequent among pupils of the high schools than among those of the elementary schools. This is the age of early adolescence, with physical, mental, and emotional changes which make these pupils more susceptible to disease in general, if not to cardiac disturbances. Goiter in high school girls with disturbed cardiac action is not infrequent. Greater application to study, greater exposure, greater likelihood of rheumatism and rheumatic manifestations, greater prevalence of nervous symptoms, and of dental decay—all predispose to organic and inorganic cardiac disease.

The indications for prevention of cardiac disease and for its relief and care so as to minimize the severity and extension of the process are practically the same as those outlined for the school age. It may be advisable to pay more attention to goiter in adolescent girls and to urge the use of small doses of the iodids, administration of which has been found successful, by many physicians.

The prevention of cardiac disease in children, as indeed of all diseases of childhood, rests upon an appreciation of the fact that the various age periods—infancy, babyhood, pre-school age, school age, early adolescence—are not sharply defined but are correlated, in that the various insults—psychic, dietetic, hygienic, etc., instituted during the early age periods produce lasting ill effects in later childhood and adult life. It may be

stated in general that the great desideratum in the prevention and care of cardiac disease in children is regulation rather than restriction.

With an increased knowledge of the actual and potential causes of heart disease in children and the possibilities of prevention, relief, and care, there has arisen a desire to afford these children specialized and more or less individual care and treatment. To this end, various workers have organized cardiac classes. These classes are of two kinds: (1) Those maintained in or adjacent to school buildings, and (2) those organized at various hospitals.

The organization of these two types of classes varies considerably. The cardiac classes maintained in schools are special classes in which groups of children affected with cardiac disease are segregated. There is no separation of the sexes and children of all grades are admitted. These classes are maintained by and under the supervision of the Department of Education. The children are afforded rest, regulation of food, limitation of study, graduated play and exercise, protection against undue exposure, etc. There are many enthusiastic advocates of this plan who say that the congenial surroundings *et al* limit further extension of the disease, prevent complications, and make the children happy. On the other hand, there are those who oppose these classes on the following grounds:

(a) That segregation has a bad psychic effect upon the children, especially upon girls. (b) That if the cardiac disease is serious enough to warrant care in a cardiac class the child is ill enough to remain at home. (c) That better supervision can be exercised by the teacher when one or two cases of cardiac disease exist in a regular class than when twenty to twenty-five cases of cardiac disease are congregated under the care of one teacher. (d) That these classes are less conducive to proper education, since one teacher is assigned to instruct pupils of various grades. (e) That the majority of children affected with cardiac disease are able, without danger, to engage in normal play and exercise, and that regulated play and exercise can be secured through the teacher when she is informed by the doctor and nurse of the indications, such as, avoidance of stair climbing, use of separate stairways, non-participation in fire drills, permission to arrive at school a little later and to leave a little earlier, etc.

In the main it is held that the advantage of the regular class for these cases is that the child is not made conscious of the fact that he is separate and apart from his fellows—a hothouse plant requiring special attention—while at the same time by careful direction he is shown the need of caution along certain lines. It is to be remembered there are many children who have physical signs of heart disease—organic murmurs—without any subjective discomforts and without other involvement of the heart. They are perfectly comfortable and require no special care. To remind them constantly that they have heart disease or to place them in cardiac classes would necessarily be detrimental. These cases call for tact and judgment as regards instruction to parents, teachers, and pupils. These children must be carefully watched and safeguarded and instructed in the rules of healthful living, without undue emphasis upon the heart condition.

In view of the division of forces among the profession in the matter of cardiac classes in the schools, it is recommended that:

A special committee be appointed by the Commissioner of Health to study this phase of the problem with a view to making special recommendations.

#### Cardiac Classes at Clinics

These are really special cardiac classes or children's heart clinics, maintained at different hospitals for potential and actual cases of cardiac disease in children. They strive to educate parents, social workers and children in preventive measures and to institute necessary remediable measures, such as graduated exercise and drills, regulated according to the working capacity of the heart or its exercise tolerance. Special days are set aside for visits to the clinics. Social workers visit the homes and efficient cooperation is established between the doctor, the social worker, and the home, provision is made for necessary operations and special examinations, and, finally for convalescence at summer homes. In the opinion of the Committee, these cardiac clinics are of great value and a step forward in the prevention and control of heart disease in children.

#### Homes for Cardiac Children

During the stage of early or late decompensation, children with cardiac disease require special care, far greater than can be afforded in the homes of the poor. The general

wards of city hospitals do not answer the purpose. In the treatment of certain cases of cardiac disease in children, the mind as well as the heart must be put at ease. Surroundings have much to do with this, and a home in the country affords an excellent opportunity. There is an insufficient supply of these homes to meet the demand. It is extremely difficult to secure admission for this type of case into the ordinary convalescent homes because they hesitate to assume responsibility as they know that it requires constant and careful supervision. The Committee therefore commends all efforts made to establish and maintain homes for children with cardiac disease, and express the hope that the number will be materially increased within the near future.

In concluding the presentation of cardiac disease in children, the Committee feels that there should be a more common and general understanding of what is meant by "heart disease" or "cardiac disease" in children. If we accept that term to convey only the old idea of endocarditis with murmurs, the number of cases will be much smaller than that which actually obtains, since it does not include other types of cardiac diseases and disturbances, such as, myocarditis, insignificant cardiac murmurs, hemic murmurs, neuro-circulatory asthenia, etc. Since rheumatism is the most common cause of heart disease in children, and since recurrent tonsillitis, chorea, growing pains, joint pains, muscular pains, are potential rheumatism, the importance of these manifestations, from the preventive standpoint, is easily appreciated, and should be the direct point of attack.

#### Recommendations

In considering the subject of heart disease in children, it is necessary not only to know the type of cardiac disease but its degree of severity. Inasmuch as a proper classification of heart disease in children will mean much, not only for the guidance of physicians but for follow-up work of the nurses and social workers in the homes, it is hoped and anticipated by the Committee that a special committee of pediatricists and internists, as suggested in this report, will be appointed to formulate a standardized classification which will be used in common by all physicians and community workers in the city and state.

(1) Consideration of the subject of heart disease from the community standpoint must be approached from

two angles: (1) cardiac disease in childhood—up to sixteen years of age; and (2) cardiac disease in adult life—from sixteen years upward. The causes—immediate, predisposing, predominating, exciting—the types of involvement, the prognosis, methods of approach and other factors, vary considerably at these different periods of life.

(2) Cardiac disease is relatively infrequent up to six years of age. Much of a preventive nature can be accomplished during this formative period. Periodic physical examinations during the pre-school age—two to six years—should be encouraged with a view to detecting and correcting remediable physical defects which predispose to cardiac involvements in later years and to educating parents as to the results of healthful living which make for healthier childhood.

(3) Approximately 2 per cent of the pupils of the elementary schools have cardiac disease—chronic endocarditis with murmur. This figure is conservative. If it were possible for the medical inspectors to conduct physical examinations under more favorable conditions and if we were to include other cardiac diseases, disturbances and abnormalities, this percentage would be somewhat higher.

(4) Cardiac disease in school children is found with increasing frequency from eight to fourteen years of age, reaching its height at the fourteenth year. This increase is very gradual. The percentage of cases is slightly higher in girls than in boys. This gradual increase in cardiac disease seems to keep pace with the percentage of chorea and nervous disease which are also found to increase from the eighth to the fourteenth year.

(5) The predominant causative factor of cardiac disease in children is rheumatism or rheumatic manifestations—chorea, recurrent tonsillitis, joint disease, so-called "growing pains," muscular pains.

(6) Education of the public as to the relation of rheumatism and rheumatic manifestations to cardiac disease, either by word of mouth or literature—will be productive of great good. It must be understood however, that such instruction must be very carefully prepared so as not to cause undue excitement or fear on the part of parents or pupils.

(7) Infectious diseases, decayed teeth and respiratory involvements are the next most frequent causes of cardiac diseases, in the order named.

(8) Children returning to school

after discharge from a departmental contagious disease hospitals and those returning to school after treatment at home for infectious diseases, should be and will be more carefully supervised in future, with special reference to the heart or to any possible complications and sequelae following these diseases.

(9) The percentage of cardiac disease is somewhat higher among high school pupils than among pupils of the elementary schools. Adolescent goiter with cardiac disturbance is comparatively frequent among high school girls and responds to small doses of iodides in many instances.

(10) Prevention of cardiac disease and in fact, of all diseases of childhood, depends upon appreciation of the fact that all age periods under

sixteen years of age are interdependent and correlated and that care and preventive measures during one period often carry on to later years.

(11) In view of the sporadic organization of cardiac classes in public schools and the division of professional opinion as to their value and usefulness a special committee should be designated to study this problem and to submit definite recommendations.

(12) Homes for cardiac children fulfill a demand and their establishment and maintenance should be encouraged and supported.

(13) The great desideratum in the prevention and care of cardiac disease in childhood is regulation rather than restriction.

## Heads Health Association

**B**OOTH by experience and personality Dr. Allan J. McLaughlin, the new head of the American Public Health Association, is unusually well qualified for the honorable post to which he has been chosen and much is anticipated of his administration.

From 1900 until 1902 he was engaged in the medical examination of arriving aliens at the port of New York. In 1903 and 1904, he served

Dr. Allan J. McLaughlin, elected head of the American Public Health Association, brings to that office a long and creditable experience in the wider issues of health administration.

at the Bureau of Public Health Service in Washington as assistant to the Surgeon General.

Dr. McLaughlin was in charge of the Federal investigation of the relation of the sewage pollution of the Great Lakes and Missouri River to the prevalence of typhoid fever, and in 1913 and 1914, was Chief Sanitary Expert and Director of Field Work for the International Joint Commission. Under his direction the sewage pollution of more than two thousand miles of boundary waters between the United States and Canada was investigated. Seventeen laboratories were established and over twenty thousand samples of water analyzed.

Dr. McLaughlin assumed charge of the Massachusetts Department of Health in 1914. He reorganized the department and remained at its head as Commissioner for a little over three years. After the entrance of the United States into the World War, Dr. McLaughlin was recalled to the Public Health Service and placed in charge of the protection of the health of the military forces in the extra-cantonment areas. Since the war he has been in charge of the Division of Domestic Quarantine, which is charged with the duty of the suppression of epidemics, bubonic plague, Asiatic cholera, typhus fever, yellow fever, and smallpox, and in the prevention of the spread of all communicable diseases from one state to another. This division is really a "States-Relation Division," and Dr. McLaughlin has utilized the state and local machinery in a system of co-operative control of water supplies used in interstate traffic and in the prevention of the spread of disease from one state to another.

## *“Vital Facts About Cancer”*

---

The JOHN HANCOCK MUTUAL LIFE INSURANCE COMPANY has joined heartily in the movement initiated by the “American Society for the Control of Cancer” to spread information in regard to cancer, especially the fact that if taken in its early stages this dread disease may be actually cured.

The Company believes that the very announcement of this policy is enough to stimulate its agents in all sections to get this idea out as quickly and as widely as possible, and we have asked them to see that every one of its policyholders and their friends have copies of our leaflet entitled “Vital Facts about Cancer.”

We believe that the more they can distribute the better, for a timely use of this leaflet may save many a valuable life.

We will be pleased to supply this leaflet to anyone desiring it upon application to the MEDICAL DEPARTMENT of the Company.

*John Hancock*

# The Psychology of Posture\*

BY FLOYD A. ROWE, DIRECTOR OF PHYSICAL EDUCATION, LANSING, MICH.

THERE can be no gainsaying the strength or truth of the statement, "A task bravely and confidently begun is half done." In actual reality this is just as true of good posture and its attainment as of any other concrete human desire. One may say that the attainment of good posture is one of the human desires which is not particularly dominant. Perhaps it is not of itself but indirectly, or in vocational phraseology, one of the by-products of good posture is a very desirable thing and its possession is often thought to be one of the most priceless of all of the human desires, simply—good health.

Now as to whether good health is an attribute of good posture or *vice versa* is beyond the scope of this article to decide. There can be no questioning, however, that good posture is an excellent index to good health. Picture, if you will, the "old folks" you know intimately and personally. Which are the ones bent over and making use of canes and other supports, and saying that their health is only "tolerable good" or that they are not as well today as yesterday, etc., etc.? Then on the other hand picture the ones who sit up straight even when resting in a rocking chair and those who walk with head up and a smile on their faces. If canes are carried by these, it is for the purpose of giving them something to carry, something to do things with, not to be of assistance in getting around. There can be no question but that good carriage and posture do very truthfully tell the story of physical energy and well being when applied, as above suggested, to our older friends and relatives.

How about the younger folks? Does the same principle apply to them?

Think again of the most attractive of your friends, the ones who stand out, the ones who attract the glances of the passers-by, the ones who are the life of the party; are they the ones who walk with their heads up and their chests up or do they go along hanging their heads and awkwardly swinging their arms? When you have done something in which you feel justifiable pride, do you slouch around with hands in pockets and eyes on the sidewalk with a frown

on your face? Well, not exactly. Your head is up, you are looking everyone in the eye with a smile on your face. Your shoulders are squared and you go about with a little spring in your step.

One step further in the age scale. Does the boy—or girl either, for that matter—who has an abundance of good health, the boy with freckles on his nose, a contagious grin, and his pockets full of marbles and other "useless junk"—does he come into the school room on his tiptoes with

and more thoughtful analysis will show that this posture-health coefficient is even greater than at first estimated. Watch your friends for a week and you will be surprised more and more to note the ever increasing mass of visual evidence you will secure which goes to prove that good posture and good health are practically synonymous.

There are other personal attributes of which good posture is an excellent index. Most of the really successful young business and professional men have good posture. Kindly note the use of the word "young" in the foregoing sentence. As age advances some of these successful young men lose their good posture

Illustrating center of gravity in correct standing posture.

an apologetic air, or does he stalk in without due respect for the presence of his dear teacher?

A rather hurried survey will tend to show that abundance of health and good posture have a very direct correlation one to the other. A further

due to lack of exercise, overeating, sitting at desks, etc., etc.

Good posture is also an index to character. You like to talk to that person who sits or stands properly and who looks at you and gives entire attention to the things you are

saying. You expect more of such a person than of one who looks at everything except the person speaking, who shifts weight uneasily from one foot to the other, or who sprawls out in a chair, crossing and re-crossing feet, or toying with every object within arm's length. You have for years associated sneak with thief and you expect the opposite in the square-shouldered straightforward person who looks you in the eye; you are seldom disappointed in your analysis of character on the above purely postural basis.

Books, leaflets, and magazine articles by the score have been written on posture, the way to secure it and how to measure it. Valuable as it is and hard as it seems to be to secure and measure—judging from all of the above mentioned articles—there seems to be one way only in which to secure a really accurate and at the same time scientifically sound measure of posture. Almost all postural defects are either caused by or are the result of the pull of gravity upon the human mechanism which we call the body. Good posture then is the result of a winning fight of the human mechanism, muscles, and will power against the pull of gravity. Poor posture is, on the contrary, the result of a losing fight between the same two opponents. Therefore if a measure of posture is desired the same can be secured by removing the body from the pull of gravity and measuring its total length. Dividing then the length of the body when standing subject to the pull of gravity by the length of the body when not subject to the pull of gravity one would get an absolutely accurate and correct mathematical percentage which would serve to measure the correctness of posture.

But you at once say that the human body cannot be removed from the pull of gravity, which is of course true; but if the body in question be placed in a supine position upon the floor there is no pull of gravity which will in any way affect its length. Measuring then the person standing and again lying and dividing one by the other we secure immediately the postural percentage of the person. This per cent of posture will vary in actual cases from 95 per cent to 99 per cent. The lower limit is of course variable and depends in individual cases upon how one is feeling at the time the standing measurement is taken. The more dejected or physically tired the individual is at the time of the measurement, the poorer it will be. Here again posture and

physical or mental feeling show a remarkably close correlation.

### Not Difficult to Attain

How to attain good posture and its corresponding benefits is no more difficult than its measurement, provided there is a "will" to do so. With adults then the "will" to attain good posture plus the knowledge of what good posture really is constitutes the entire program, for "to will is to do" in this instance. With children, however, good posture is really a natural state of existence. Children are forced into unnatural and harmful postures by attendance at school and by many of the tasks about the home. Without question, the greatest element which enters into the making of poor posture among children is that of mental attitude. Ask a child to perform some task which is considered disagreeable and which the child does not wish to do. The first symptom of unwillingness is facial, followed by a bodily slump in posture. The head is hung, the shoulders dropped, and the entire posture of the child instantly suffers because of the mental reaction. Offer a suitable reward for the accomplishment of the task, however, and there is an immediate reversal of posture. In school parlance, then, motivate the work for the child in order to lift it out of the class of drudgery.

This same difference can be found between the way a child gets out of bed on school mornings and on Saturday morning. There is a decided difference in both mental and physical posture or attitude. Willie has to be repeatedly called on the school morning, and when he finally appears he has a hang-dog look; he does not

enjoy his breakfast, much less the regulation face washing, tooth brushing, etc., preliminary to it. But on Saturday morning, "Oh, boy!" Willie is up and coming, he actually splashes water about when he washes, and his breakfast disappears as if by magic, he can even be persuaded to run cheerfully an errand or two before he is allowed to start in on a day of unalloyed pleasure. Saturday morning, Willie has good posture; he has it as a natural physical attribute; he has it in the superlative degree and without thought or without admonition from his parents.

Any book, monograph, pamphlet, or magazine article ever written upon posture has much to say regarding position of the chest, shoulders, abdomen, chin, head, arms, etc., etc. The usual commands or directions are about as follows: Head erect; chin in; chest up and out; abdomen flat or in; shoulders back; weight on the balls of the feet. The average person trying to get good posture from commands of this sort assumes exaggerated position which is positively deforming and which is so unnatural as to be extremely bad for everyone. This exaggerated position is hard indeed to correct, as one instinctively feels that posture to be good must be "felt" and one surely feels, or is conscious of this position assumed upon hearing or thinking of the ordinary directions given.

### "Prick Your Ears Up"

Several years ago Dr. C. Ward Crampton used one expression among many others regarding posture and the way in which good posture was to be assumed which seems to be without a fault or possible criticism

Seats not large enough cause students to assume faulty posture.

## How the Right Shoes Increased Her Sales

*A true story with a lesson for all men and women*

"MISS GREEN, you and eight other girls out of seven hundred have shown increased sales during the last three months. All the others show losses. Why have you been able to increase your sales?"

"Who are the eight girls?" asked the young woman.

The president of the store read the names. The girl seemed happy to answer:

"Shoes—Cantilever Shoes. I got them first. Later I took each of those girls, in turn, to the Cantilever Shop. In Cantilevers, you see, our minds are off our feet. The business gets all our attention. We don't feel cross, cranky or tired. I suppose that's why our sales are good."

That afternoon the president of the big store walked into the Cantilever Shop and asked a salesman to explain the features of Cantilever Shoes.

The Cantilever salesman took a shoe and bent the sole at the shank, showing how the shoe

conforms to the human foot, even to having a flexible arch like the foot. He said, "the arch of the foot should flex with every step, according to nature, yet ordinary shoes are made rigid by a concealed metal shank-piece that forbids free movement of the muscles. There is no rigid shank in Cantilevers. The 'waist' is designed to hug the instep, the shoe fits and supports the arch restfully. The flexibility allows the arch muscles free play and this, together with the natural lines of the shoe, permits perfect circulation.

"It is important to allow the foot muscles to exercise, to keep well and strong. The forepart of a Cantilever Shoe is shaped to look well, while allowing the toes to lie in their normal position. Cantilever heels are moderately high—high enough to be smart, without throwing the posture of the body out of balance as exaggerated heels do, causing unnatural pressure and strain on the nerves and the internal organs. By wearing Cantilever Shoes a woman avoids headaches and backaches, irritability and nervousness. She is brighter and happier."

"The subject is of great importance to the business woman who is required to stand during the greater part of the working period. The tired feeling often complained of at the end of the day's work may be attributed to ill-fitting shoes."

—Dr. Wilmer Krusen, head of the Department of Public Health of Philadelphia.

"Pain is a great foe to good looks. Comfort works just the other way. If you are comfortable, you are apt to be pleasant, and pleasantness and prettiness are often synonymous terms. Eliminate as many of your worries as you conveniently can—and your tight shoes."

—Grace Margaret Gould on "Good Looks" in Woman's Home Companion.

"Working women are the worst offenders. It is the girls who are on their feet most who persist in wearing the highest heels. Sensible women have learned that they can increase their efficiency and even earn bigger salaries by wearing shoes built for solid comfort and health."

—Dr. Evangelino W. Young, of Boston.

If no dealer listed at the right is near you, the Manufacturers, MURSE & HUPP (111 No. 1 Carlton Avenue, Brooklyn, N. Y.) will mail you the Cantilever Shoe Booklet and the address of a nearby dealer.

when it comes to directing anyone, either adult or child, to assume a pleasing posture. This one command it would seem embodies both the physical and mental attitude of good posture—for good physical posture must be accompanied by good mental posture to be effective. This command is simple, straightforward, and direct. Try it yourself and see if it has the desired effect. "Prick your ears up." Simple, forceful, direct and full of suggestion.

Try this on the children; it appeals to them; they appreciate it and respond to it immediately. Their heads, necks, shoulders, chests, abdomens, arms, hands, etc., etc., fall into naturally correct positions for let us repeat again—good posture is a natural physical adjunct, not an assumed position.

"Prick your ears up." That is a

command which is full to the brim of wonderful suggestion and possibility. Close your eyes and picture just what it means. Prick your ears up physically and mentally; what more is necessary? Immediately you are in a position of mental and physical expectation ready to hear, to think, and to act; and, after all, good posture is the natural physical and mental attitude of the person who has accomplished things and is poised ready to accomplish many more wonderful things. Let us then go forward this school year with that confident attitude which makes the hard things easy and which assures us of victory. Let us at all times keep our minds and bodies, and those of the children as well, in the right posture—that of eager expectancy typified by the command—"Prick your ears up."

## Radiant Energy of the Sun

THE radiant energy supplied by the sun in the form of light and heat is the agent Nature places at the service of animate and inanimate matter for the conservation of its individuality, for its defense, and for the continuation of the species, according to Dr. A. A. Nouel. In some way variously explained but not precisely understood direct sunlight sets in motion a recuperative process which restores the deformed bodies of children who suffer from bone infection, and later observations would seem to show curative properties of sunlight in such diseases of alimentation as rickets. It is known that the infra-red rays have a powerful bactericidal action and, owing to their greater wave length, they give out a considerable amount of heat when they impinge upon the body. On account of their heat the red rays are also active in vaso-dilatation, which favors phagocytosis, and tends to relieve congestion in the internal organs. These facts are often overlooked when attempts are made to find in ultra-violet rays an artificial substitute for sunlight.

In seeking an explanation for the superiority of whole sunlight in this treatment, Rollier says that, in view of the fact that in Nature we so frequently meet with organic substances or living cells which are affected by wave lengths varying between definite and comparatively narrow limits, it seems not improbable that similar conditions apply to the human body, and that certain rays act on one type

of cell and quite different ones on another.

The stimulating effects of sunlight treatment are unmistakable. The splendid muscular development usual with heliotherapy, even in patients confined entirely to bed, Dr. Rollier attributes to direct stimulation, probably of an electrical nature, as vascular changes alone would hardly seem a sufficient explanation. Whole sunlight, elevation, and pure atmosphere give the best results, but there is value in light treatment by artificial means. Lamps giving a maximum of ultraviolet rays have been successfully employed and in some hands are quite successful.

## Congress to Consider Fess-Capper Amended Bill

The Fess-Capper Physical Education bill as amended will be considered during the regular session of Congress. The bill provides for the extension of financial aid to the states for the purpose of stimulating adequate health training and physical education for all school children.

The money which is appropriated is to be spent for the preparation and training of supervisors and teachers of physical education, including school health supervisors and school nurses, through state normal schools and other institutions equipped for such service.

Ten million dollars is appropriated for the fiscal year ending June 30, 1922, and for each subsequent year an amount sufficient to allot one dollar per child of school age to each state which has accepted the provisions of the act. These appropriations are to be allotted in the proportion which the population of each state between the ages of six and eighteen years, inclusive, bears to the total population of the United States between the same ages.

For the purpose of administering the act, in the Bureau of Education of the Department of the Interior, a Division of Physical Education is established under a director of physical education. The Bureau of Education, the agencies designated by the states and the United States Public Health Service are from time to time to make studies, investigations, and demonstrations relating to the health supervision of children of school age and the sanitation of school buildings, equipment, and grounds.

Wide World Photos.

A hospital has been erected on the former "exercise place" in the Schweder Strasse, Berlin, where the deformed Children of Berlin can be treated for diseased bones and sick bodies. The entire treatment consists of fresh air and plenty of sunlight. Photo shows the girls' section of the hospital taking the sun cure.

# Sherman's Polyvalent Vaccines

A more adequate and rapid immunity can be established with polyvalent vaccines than from an infection itself. SHERMAN'S POLYVALENT VACCINES rapidly stimulate the metabolism and defense of the body with a resultant prompt recovery in general acute infections.

Given early, bacterial vaccines almost invariably cut short the common pyogenic infections of the skin, mucosa joints and tissues;

Administered in advanced cases, they usually ameliorate or abbreviate the course of the disease;

Even when used as a last desperate expedient, they often reverse unfavorable prognosis.

The immunizing powers of stock vaccines are demonstrated by the prophylactic efficiency of typhoid vaccine. Bacterins made from selected, vigorous organisms are far higher immuno-producers than autovaccines prepared from feeble, degenerated organisms sometimes found in the patient's own specimens. Especially in acute cases, the PROMPT injection of a stock bacterin is decidedly preferable to the DELAYED injection of an autogenous one. The place for autovaccines is in chronic infections which fail to clear up under stock bacterins due to the prob-

able presence of some unusual bacterium.

Advanced inflammatory processes due to only one class of bacteria are rare, mixed infections being the rule. Therefore, COMBINED VACCINES, containing all strains likely to be present, give the best assurances of success; an unneeded variety of the bacterin is harmless and in no way weakens therapeutic response.

Thus the favorite invaders of the nose and throat are the pneumococcus, the streptococcus, the staphylococcus and the micrococcus catarrhalis, calling for Sherman's No. 40, and in chronic cases—when there is a foul odor produced by the Friedlander bacillus—Sherman's No. 36. In visceral infections, due chiefly to the colon bacillus with the pus cocci, Sherman's No. 35 is appropriate. In Neisser infections, if these organisms are not already allied with the gonococcus, the imminence of their entrance is so great that the rational combination is Sherman's No. 49.

When, particularly in grave cases, valuable time may be lost in securing the variety of vaccine especially recommended, it is always advisable to use the vaccine at hand which contains the predominant organism of the disease to be combatted.

## Sherman's 10 Mil Container

This package has many superior features which assure asepsis, prevent leakage and facilitate the removal of contents. It is constructed on the well known Sherman principle.

The vial is amply strong which prevents breakage so frequent with shell vials.

We are exclusive and pioneer producers of Bacterial Vaccines. Originators of the aseptic bulk package. Pioneer in elucidation, experimentation and clinical demonstration.

Twenty Preparations.

# Physical Education in Colleges\*

By GEORGE L. MEYLAN, M.D., CHAIRMAN, COLUMBIA UNIVERSITY,  
NEW YORK CITY

**Y**OUR committee, appointed in 1909, takes great pleasure in reporting that the questionnaire sent to the colleges in 1920 was answered more carefully and by a much larger number of colleges than the previous questionnaires sent out in 1909 and 1915.

The data contained in the answers to this questionnaire constitute a fairly complete report of the present status of the organization, equipment, and administration of physical education and athletics in American colleges. This happy result is due to two chief factors. (1) Greatly increased interest and development in college physical education and athletics during the last five years; and, (2) the generous cooperation of the United States Bureau of Education in duplicating, mailing, and collecting the questionnaires.

Your Committee recommends that the complete data be published in tabular form and made available to college presidents, directors of physical education, and others interested in college physical education and athletics. The data collected in 1909 and 1915 have been used with exceedingly good results by college directors of physical education in securing academic recognition and financial support for physical education. . . .

The complete data contained in the 1920 questionnaires have been tabulated and the material is ready for publication. It is not feasible at this time to present more than a résumé of the most important facts as follows:

260 questionnaires were returned.  
250 questionnaires were filled out sufficiently to be used in the tabulation.

56 are from institutions for men only.

50 are from institutions for women only.

144 are from co-educational institutions.

## Physical Education

(1) Have you a department of physical education?

236 answers. 199 or 84.3 per cent, yes.

(2) Activities administered by department of physical education:

(a) Gymnasium, 200, or 85 per cent.

(b) Instruction in gymnastics and athletics, 203, or 86 per cent.

(c) Coaching and training of varsity teams, 194, or 82.2 per cent.

(d) Business administration of inter-collegiate athletics, 95, or 40 per cent.

(e) Instruction in hygiene, 90, or 38.1 per cent.

(f) Care of students' health, 118, or 50 per cent.

(g) Sanitation of college community, 54, or 23.3 per cent.

(3) Rank of officers in department of physical education:

(a) Professor . . . . .157

(b) Assoc. or assist. professor. 93  
(a and b equal 56.4 per cent of colleges.)

(c) Physical director . . . . .170

(d) Instructor . . . . .261

(e) Assistant . . . . .208

(f) Clerk . . . . . 99

Average number on instruction staff, 3.8 per college.

(4) Has head of department a seat in faculty?  
213 answered. 187, or 88 per cent, yes.

(5) The following figures were obtained concerning equipment:

209 colleges have 270 gymnasiums.

89 colleges have 243 handball courts.

16 colleges have 39 squash courts.

62 colleges have 103 courts for boxing, fencing, etc.

90 colleges have 101 swimming pools.

205 colleges have 331 baseball fields.

179 colleges have 246 football fields.

100 colleges have 148 fields for other games.

160 colleges have 203 running tracks.

201 colleges have 1,240 tennis courts.

18 colleges have 25 boathouses.

20 colleges have 249 boats.

19 colleges have 26 skating rinks.

(6) The statistics on the number of students enrolled and the annual budgets in the department of physical education follow:

(a) Physical education facilities provided:

86,199 male students provided for by 162 colleges.

49,462 female students provided for by 130 colleges.

(b) Students enrolled in prescribed physical education courses:

43,350 male students in 126 colleges.

31,666 female students in 113 colleges.

(c) Students enrolled in elective

physical education courses:

5,913 male students in 60 colleges.

4,074 female students in 42 colleges.

(d) Students participating in intercollegiate athletics:

19,120 male students in 175 colleges.

1,002 female students in 19 colleges.

(e) Students participating in intramural athletics:

37,683 male students in 131 colleges.

30,423 female students in 71 colleges.

(f) Number of physical examinations made:

44,231 examinations of male students by 98 colleges.

26,115 examinations of female students by 84 colleges.

(g) Annual budgets for departments of physical education:

126 colleges expend total of \$800,855.

Average amount of budget \$6,356.

Largest budget \$47,000; smallest \$100.

## Physical Education Courses

(1) 180 colleges have prescribed courses in physical education.

85 colleges have elective courses in physical education.

(2) The courses are prescribed as follows:

To freshmen at 157 colleges.

To sophomores at 137 colleges.

To juniors at 44 colleges.

To seniors at 29 colleges.

(3) Positive credit is given for physical education courses by 139 colleges.

(4) 134 colleges permit students to substitute training with a varsity or freshman team for the required work in physical education.

## Athletic Administration

(1) Two hundred and two colleges report that they participate in intercollegiate athletics.

(2) The administration of varsity teams is by:

(a) The college exclusively in 40 colleges.

(b) The students exclusively in 60 colleges.

(c) The college and students in 108 colleges.

(d) The college, students and alumni in 62 colleges.

(4) The coaches are appointed and paid by:

(a) The college in 159 colleges.

(b) The athletic association in 47 colleges.

(c) The college and the athletic association in 20 colleges.

(7) 188 colleges report that they are in favor of the plan advocated by the National Collegiate Athletic Association to have all intercollegiate athletics controlled by the college authorities.

## Health Work in Many Lands

THE health activities of the Rockefeller Foundation as recounted in their Seventh Annual Report covering the period from January 1, 1920, to December 31, 1920, offer an excellent demonstration of the efficacy of precise method along definitely directed lines. Whether their program aimed at tuberculosis in France, yellow fever in Guatemala, malarial control in Argentina and Nicaragua, or hookworm disease in Papua, the method was the same—a preliminary survey of the local conditions, the collection and dissemination of all the available knowledge of the causes of the prevailing disease, organization of trained men for health administration, and the promotion of cooperative effort between the individual, the community, and such health organizations.

That consistent effort of this kind may be counted on to bear results is sufficiently clear from the tabular summary of results, which show so high a percentage of cures in given campaigns as to appear, on the surface, as an incrimination of health agencies which usually register a lower record.

There is much to be said in this connection, however. Knowledge of the causes of disease is one thing, and its application to control the spread of maladies is another. The Foundation has stated that even at best the public authorities can control wholly or in part only about 20 per cent of the diseases by which people are crippled or killed. Typhus, scarlet

fever, smallpox, and malaria can be either prevented or kept from spreading; but tuberculosis, measles, diphtheria, pneumonia, and influenza cannot be placed in the same category as their control must remain more the initiative of the community and the individual than of organized health activity, which is one way of saying that the community controls its own death rate.

### The Toll of Yellow Fever

Certain disorders that take a heavy toll and that ignore all political boundary lines have been the especial concern of the International Health Board. The fight against yellow fever, for instance, was carried on during 1920 in all infected areas: on the east coast of Brazil; in Ecuador and Peru; in Guatemala, Honduras, Nicaragua, and Salvador; in Mexico; and in West Africa. The studies in Africa aim (1) to determine whether the reported yellow fever in that region is yellow fever; and (2) to ascertain, if the presence of yellow fever should be confirmed, whether control measures are feasible.

As a result of the laboratory studies of Noguchi, a therapeutic serum is available for the treatment of yellow fever which, given in the early days of the disease, has seemed to reduce the usual mortality of 50 to 60 per cent to 9 per cent, supplementing a thorough-going mosquito control.

Based upon the successful results attendant upon earlier field experiments, demonstrations were carried

Worms recovered from nine-year-old boy as result of one treatment with oil of chenopodium. Eighty-nine hookworms and eighty-one Ascaris. This demonstration induced many in Brazil to apply for treatment.

out in fifty-two towns in southern states to prove that even in towns of 1,000 to 1,500 inhabitants under average conditions, malaria can be controlled within limits of cost which such communities may well afford. At an average per capita cost of seventy-eight cents per annum—an amount much less than the cost of malaria in doctors' bills alone. A statistical measurement of the results from malaria control are difficult to obtain, but the best estimate available would seem to indicate that malaria incidence has been lowered from 40 per cent in 1917 to 18 per cent in 1920.

### Hookworm Control

Hookworm disease affects fundamentally the welfare of mankind over

A group of village headmen assembled to hear a lecture on hookworm disease

# A remarkably efficacious remedy in furunculosis

*The curative effects of yeast  
described by physicians and physiological  
chemists*

The successful use of yeast in certain maladies has been demonstrated by careful tests. In leading institutions in New York and Philadelphia the yeast treatment was given in 17 cases of furunculosis.

The tests were carried on under the direction of Philip B. Hawk, Ph.D., by Frank Crozer Knowles, M. D., Martin E. Rehfuß, M. D., and James A. Clarke, M. D., with the collaboration of Olaf Bergeim, Ph.D., H. Rodell Fishback, M. D., Sc.D., Clarence A. Smith, Ph.D., and Robert A. Lichtenthaler, M. S.

The cases covered such conditions as single large boil; boils a week apart for two months; and periodic boils for years. One patient had several large boils which did not yield to vaccine. After three cakes of yeast daily for two weeks the boils disappeared. A boil started on the leg after yeast was stopped. The yeast treatment was resumed. The boil soon cured.

Fleischman's Yeast was used throughout the investigation—as being not only the most readily available, but also because it gave assurance of absolute uniformity and purity.

The conclusion of Dr. Philip B. Hawk and his associates is: "In furunculosis, yeast is a remarkably efficacious remedy. Its curative action in these cases is no

doubt aided by the leukocytosis which is developed."

The usual dosage in these cases was three cakes a day—suspended in water, beef-tea, or orange juice—generally before meals. In some cases, because of the laxative action of the yeast, it was necessary to reduce the dosage.

With patients troubled with gas formation, it was found preferable either to administer yeast between meals, or else to "kill" the yeast by placing it in boiling water for a few minutes. The action of the "killed" yeast proved to be much the same as that of the living yeast.

A full report of this test can be found in the Journal of the A. M. A. for October 13, 1917, under the title: "The Use of Baker's Yeast in Diseases of the Skin and of the Gastro-Intestinal Tract."

Fleischmann's Yeast may be obtained fresh daily from all grocers. Physicians may write to The Fleischmann Company in the nearest large city and a supply will be mailed direct on the days wanted.

THE FLEISCHMANN COMPANY, 701 Washington Street, New York, N. Y.

Carrying the gospel of sanitation to native peoples. Attendance at lecture on hookworm disease. Village of Gamilababa, Trobriand Islands, Papua.

vast regions. The development of permanent agencies for its control were undertaken during 1920 in nine southern states and in twenty-five foreign states and countries. The appendix of the report gives graphs and tables showing the extent and severity of hookworm disease, and the working plans for its control, and the progress made toward organizing effective permanent agencies which would operate in this field over long periods of times.

The importance of this work in the South is stimulating county health work. Hookworm disease is not eradicated but effective machinery for its control is in operation,

and the lessons driven home by this campaign in the interests of preventive medicine has reflected in lowered death rates from other causes, in North Carolina a reduction has been registered in the typhoid death rate alone from 29.6 to 16.9 per 100,000.

No better evidence is offered anywhere of the present trend in medicine to shift from official action to popular education, that is, from cure to prevention. The best safeguards of health are found through team work between scientific research and popular effort, guided by the socially minded physician. Popular sentiment for public health must be stimulated.

## Experiments in Ventilation

THE Pittsburgh Experiment Station of the United States Bureau of Mines is working in cooperation with the Research Bureau of the American Society of Heating and Ventilating Engineers on a number of important problems which affect each individual in his home life, in his place of business, and especially in those places where many people congregate, as in churches, school-rooms, and theaters. It is important to ventilate such places with sufficient fresh air to make everyone comfortable enough to be able to work at high efficiency. The circulation of excessive quantities of fresh air imposes a considerable cost on the heating system, therefore an efficiently designed heating and ventilating system introduces the least amount of cooled air consistent with proper conditions for health. In this connection the use of ozone has frequently been proposed and actually tried in a

number of places. The ozone is supposed to deodorize and purify the air by the oxidation of organic matter and possibly by killing bacteria.

It is, however, a real question as to whether ozone can be introduced in quantities large enough to kill bacteria without producing very serious irritation of the throat and lung tissues. It is also a question as to whether harmful oxides of nitrogen are not produced simultaneously with ozone. Definite information is needed on this subject. The first step in obtaining such information is to work out methods for accurately determining the percentage of ozone and oxides of nitrogen produced for different types of ozone machines and to develop suitable methods for determining the very small quantities of ozone and oxides of nitrogen that may be present in air treated with such machines. Analytical work of the highest precision is required. The

gas laboratory of the Bureau of Mines, Pittsburgh Experiment Station, is now engaged on this problem, working in cooperation with the Research Bureau of the American Society of Heating and Ventilating Engineers which is housed in the same building.

After the chemists have worked out the methods of detecting and analyzing these small quantities of ozone and oxides of nitrogen, the next problem will be undertaken in a like cooperation of the two agencies just named working with the United States Public Health Service. Surgeons from this service are detailed to the Bureau of Mines for working on health and sanitation problems. Many facts belonging to industrial hygiene will be brought out in the study. The work is being carried on under the joint general direction of A. C. Fieldner, supervising chemist and superintendent of the Pittsburgh Station of the Bureau of Mines, and Dr. R. R. Sayers, chief surgeon, Bureau of Mines, by G. W. Jones, assistant gas chemist, Bureau of Mines; W. P. Yant, assistant analytical chemist, Bureau of Mines; and O. W. Armspach, engineer, American Society of Heating and Ventilating Engineers.

## The Subjective Element in Fatigue

In estimating strains and tax upon nervous energy and vitality, there are, in addition to concentrated attention and intensity of effort, four factors which contribute in no uncertain measure. They are speed, noise, complexity, and monotony. Pressure of any kind, not included within this group, should be added as a fifth. The consciousness of ever present supervision may produce a nervous strain upon sensitive workers greater than that of the speeding up of machinery, the incessant din of hammers, or complications of intricate industrial operations. To a pressure of employment at one time and uncertainty of employment at another there must be added, in the case of many a wage earner, ever present trying circumstances and responsibilities. Thus far in industrial regulation, the cumulative effects of subjective influences and of combined physical and mental strain have been all but wholly ignored. They are the very essence of the forces which are helping to undermine, not alone the health of hundreds of thousands of individuals, but also the vitality of coming generations.—W. L. Mackenzie King.

## Curative Fresh Air for School Children

At first restricted to the definitely tuberculous child, fresh-air therapy is now being applied through fresh-air camp schools to the weak and undernourished with gratifying results. Its curative effect has been demonstrated in cases of anemia, malnutrition, rickets, general deficient development, and convalescence after acute general fevers.

The converse development of the fresh air school from elaborate and expensive residential establishments far from the child's locality to sheds with roofs and no walls located near the industrial centers is shown by Lina M. Potter in a recent issue of the *International Journal of Public Health*.

Fresh air classes first developed in England when classes were started in hospitals for sick children. Philanthropic societies saw the need of the weak school child for more air and by summer outings attempted to compensate him for his lack of fresh air during the school year. In the last few years these various attempts to ameliorate the conditions of the weakly and sick school child have been coordinated.

Government fresh-air schools have been provided in crowded and industrial districts. The types of child eligible for treatment are the early pulmonary tuberculous, the chronically tuberculous who do not need active treatment and who have no postural requirements inconsistent with the simple school equipment, and in addition, debilitated, weakly, and ill nourished children.

There is still a great dearth of open air schools in England. According to an estimate of the London County Council for 1920, two thousand places are needed in fresh air schools for non-tuberculous children; 410 places are already provided with a proposed accommodation of 600, leaving 990 children unprovided for.

Even in London, the climate of which is notoriously uncertain, the doctors reported a "remarkable absence of catarrhal conditions in the children educated in the open air compared with those remaining in the school buildings."

Paris opened its first open air school at Chartres in 1918, its original purpose being to get children away from the war influence. Another school was founded later near Sceaux.

Fresh air therapy as applied to the school child is inexpensive and widely

applicable to all districts, is Miss Potter's conclusion.

Providence, R. I., claims the distinction of having the first open air school in the United States. Fresh air schools were soon established in New York City, Boston, Pittsburgh and Cambridge, Massachusetts. Chicago's first outdoor school for tuberculous children was started in 1909 through the joint cooperation of the board of education and the Chicago Tuberculosis Institute. So successful was the experiment that the principal of the school conducted on the

roof of the Mary Crane Nursery extended the open air project to his own building, leaving the windows of two rooms open. The children were allowed to keep their wraps on, temperature was maintained at 45 or 50 degrees Fahrenheit, and the children were given more physical activity. Of the 90 pupils in the two rooms only two had nasal discharges at the end of an eight week's period while in the other two rooms heated and ventilated in the usual way 40 pupils had nasal discharges at the end of the same period.

## Harvard Scientists to Peru

Great interest attaches to the recent expedition that went out from New York to undertake at Cerro de Pasco, Peru, a point in the Andes at a height of more than fourteen thousand feet, the first studies ever made to determine the

It is believed that the facts to be secured about the way in which the body adapts itself to a reduced supply of oxygen will prove useful in the treatment of certain diseases of the heart and lungs in which strikingly similar conditions occur. The

Keystone View Company.  
Five Harvard men (left to right) Doctors Henry S. Forbes, C. A. L. Binger, Alfred C. Redfield, Arlie V. Bock, and George Harrop, together with three medical investigators from England, left in November for Peru to carry on studies relating to the physiological effects of high altitudes.

physiological changes which enable people to live permanently in high altitudes. Their observations will include the changes in the heart, circulation, respiration, and the chemical composition of the blood which enable the natives to live in comfort and do arduous work in the copper mines at an altitude in which persons not so adapted would be incapacitated from most activities of the sort on account of the rarity of the air. The town is one of the loftiest places on the globe where any considerable number of people live.

problem is also of interest to aviators, who frequently suffer from the effects of flying at high altitudes. Fatigue is the true source of physiological troubles from rarefaction of the atmosphere. Breathlessness is produced with much less mechanical work than is possible at lower levels. Amar reports that in the Caylloma mines, South Peru, at 4,500 to 4,900 meters above sea level, the work of smiths, carpenters, wood workers, and mechanics is lowered by half. Cold, fatigue, lack of oxygenation of the blood and, perhaps, the fear of danger, produce altitude sickness.

# LOESER'S INTRAVENOUS SOLUTIONS

## RESISTANCE

The most acceptable measurement or indication of resistance and recuperation is a high Red Cell Count and Hemoglobin Index.

## AMERICAN COLLEGE OF PHYSICAL EDUCATION

*Accredited—Co-educational*

THE profession of Physical Director and Playground Supervisor is in the ascendancy. It makes possible the American ideal of "Efficiency through Fitness." One-half of the states require teaching of physical education. Therefore, Colleges, Universities, Public and Private Schools, as well as Summer Camps, Athletic Clubs, Industrial, Social and Community Centers, Banks, Manufacturing Plants, Department Stores, Y. M. and Y. W. C. A., are making constant demand for more trained men and women. The American College prepares and places through its free graduate placing bureau large numbers of these workers each year.

The American College offers two year, three year, and degree courses. We also offer a graduate placing bureau for the benefit of not only the graduates, but also for the employers of teachers of physical education. This service is rendered without cost to the student or the employer.

NEW TERM OPENS February 7, 1922.  
Write for catalog and book of views.

Address, Dept., N. H., 4200 Grand Blvd., Chicago, Ill.

## Homes Cause Ill Health

HOME conditions rather than long hours or overwork are charged with much of the poor health, so prevalent among the industrially employed girls today, said Dr. Kristine Mann, recently, head of the Health Center for Women at 5 Livingston Place, New York. On the basis of an examination recently completed of more than 1,000 women and girls engaged in gainful occupations in factories and business houses, Doctor Mann points out that industrial conditions are not the only factors in the rapid deterioration of health among the girls. Unhappy home conditions and maladjustments to life generally rank as important handicaps, she said.

"Many of our so-called working girls suffer acutely from unhappiness and friction in their family lives," Doctor Mann said in a talk at the Health Center, where she is daily and nightly helping girls and women back to better health.

"A girl's health depends very greatly on her mental attitude; if she is suffering from mental strain, there is bound to be a marked reaction in her physical condition.

"The physical condition of the average woman in industry is decidedly bad," she continued, "the worst feature being her marked tendency to develop physical ills and weaknesses

from the time she enters employment, largely due to the expenditure of her free hours and lack of exercise. The average employed woman at thirty has developed flabby muscles, tired back and eye-strain that were unknown to her when she took her initial step into employment. The average stenographer at twenty-five, our records show, does not begin to have the strength that was hers at twenty. Yet nature intended that her muscles should show the five additional years of development and strength.

"Of the thousand women from different types of work whom I examined, only 15 per cent had what might be called good posture. Fifty-three per cent suffered from various forms of indigestion. Fifty-five per cent complained of periodic headaches, many due to the need of glasses. Undoubtedly, long hours and over-pressure on the worker have done much to bring about this condition, but the fact that most of these girls spend their entire lives in cities, haunting the movie palaces at night, consuming ice-cream sodas and cheap candy, instead of indulging in strength-building exercises which can do much to relieve that tired, cramped feeling that is bound to exist at the end of a long day spent over a machine or behind a department store counter, must not be overlooked."

are placed by boarding-out agencies shall conform to the standards established by the State Board of Charities and Corrections for family boarding homes.

(4) *Physical Examination.*—A thorough physical examination shall be made of each child within a week's time of its reception by the child-placing agency, with prompt correction of remediable defects.

(5) *Mental Examination.*—A mental test should be made in all cases. It must be made in all doubtful cases.

(6) *Supervision.*—Each society shall maintain an adequate supervision of the children placed by it. It should aim to visit each child once a month.

(7) *Records.*—Each society should keep an accurate record for each child in its care, covering complete family history, physical and mental condition, and school progress.

(8) *Reports.*—Each society shall render an annual financial and social report on forms prescribed by the State Board of Charities and Corrections.

Each society shall furnish to the State Board of Charities and Corrections monthly reports of placements made and foster homes used and discontinued. A report shall be made also of each ward of the society not visited within the month.

(9) *Adoption.*—No agency should consent to the adoption of any of its wards until the child has been in one home under the supervision of the agency for at least six months.

Attention is called to the provisions of Section 224 of the Civil Code relating to persons whose consent is necessary to the adoption of a minor child and requiring that when a child has been relinquished by its parents for the purpose of adoption, a copy of the relinquishment must be filed with the State Board of Charities and Corrections prior to the commencement of adoption proceedings.

### Boarding Houses

(1) *Definition.*—A family boarding home for children is a private family home which accepts one or more children to board.

(2) *Number of Children.*—(a) Since the family boarding home is primarily a home, the number of children in it shall not exceed that number which it is customary to think of as constituting a normal family group. The number of boarded children should not exceed six.

(b) Unless especially equipped for the care of infants alone, not more

## Child-Placing Agency Standards

WITH the realization that institutional care for children does not sufficiently approximate the home conditions that augur best for the child's health and mental development, investigations have been conducted in various communities revealing conditions that, with the lack of regulatory standards and with insufficient supervision, have become intolerable. Notable success has attended clean-up measures in Kansas, and recent reports from Toronto confirm in the most indisputable terms the advantages of regulated placement over the segregation of great numbers of children in institutions.

California has outlined in the following standards, revised in March, 1921, for child caring agencies which constitute the rulings of the State Board of Charities and Corrections:

(1) *Organization.*—Each society should be incorporated; it should have a board of directors made up of

persons generally recognized as responsible citizens, persons willing to do active work for the society and representing the several religious faiths of the children in ward; and each society should have a committee which should direct the policies concerning the placement of children. There must be a superintendent who must not collect his own salary, but devote all his time to the organization and conduct of the work.

(2) *Receiving Home.*—If the society maintains a receiving home for its ward, this home, if of institutional type, shall conform to the standards adopted by the State Board of Charities and Corrections for children's institutions. If children are placed in boarding homes pending permanent placement, these homes must conform to the standards set by this Board for family boarding homes.

(3) *Foster Homes.*—In general, the foster homes in which children

than two infants shall be allowed in any family boarding home.

(3) *References.*—Satisfactory references must be furnished.

(4) *Register.*—A register shall be kept in which shall be recorded the name, age, sex of the child, the names and addresses of parents or guardians, religion, date of reception, date of discharge of each child; also a health record showing condition of the child on entrance to home and any subsequent illness or accident. Such a register has been prescribed and printed by the State Board of Charities and Corrections and is supplied free of charge. This register must at all times be open to the inspector from the State Board of Charities and Corrections.

(5) *Housing.*—(a) The home shall conform in building and maintenance to the sanitary ordinances of the city or county, and shall have the permit or endorsement of the local board of health or health officer.

(b) The house must be in a residential district (not commercial or factory), convenient to school, with sufficient room to accommodate the family group and the boarded children in a comfortable and sanitary way, and with yard space large enough for a home playground for the children.

(c) Sleeping rooms must afford at least four hundred cubic feet of space for each occupant, and must have plenty of windows opening upon street or yard—no dark courts.

(6) *Care of Children.*—(a) The dietary shall be up to the standard approved by the State Board of Charities and Corrections and should include at least one pint of milk daily for each child. Formulae for feeding infants should be prescribed by a registered physician.

(b) Each child shall have a separate bed. Each bed shall have a good spring, clean, comfortable mattress, adequate bedding, and rubber sheeting for infants and bed-wetters.

(c) Proper medical supervision shall be guaranteed each child.

(d) Individual hair and tooth brushes, towel, etc., should be provided and each child instructed in their use.

(e) Every child of proper age shall be given opportunity to attend Sabbath school or church of the religious faith of its parents.

(f) Children under fourteen years shall have no routine work other than school tasks, but there is no objection to their performing simple duties, providing these do not interfere with ample opportunity for school and play.

(g) During the absence of the foster mother, children must be left in charge of a competent person.

(7) *Income.*—The sum paid for the support of the children shall not be the only source of income for the family group; there must be some other resource.

(8) *Adult Boarders.*—No adult male boarders or roomers shall be permitted.

(9) *Removal of Children.*—When a child is given up, it must be to the parent, guardian, or other person having a legal right to receive it.

(10) *Reports.*—(a) The death or serious illness of any child must be reported promptly to the State Board of Charities and Corrections.

(b) Any change in the management or address of the foster home must be reported to the State Board of Charities and Corrections.

(c) Failure to make these reports may constitute cause for revocation of license.

### Ohio State Institutions

The report on state institutions prepared by the Ohio Board of Administration for the past year points out various needs and requirements. New housing facilities for the insane, epileptic, feeble-minded, penitentiary and reformatory institutes are imperative. In one institution 240 inmates are sleeping on the floor. It is suggested that these buildings be simple, attractive and sanitary—not the massive monumental type heretofore to such an extent used.

Although millions of dollars are annually spent for the care of an ever-increasing number of insane, feeble-minded, epileptic and criminal persons, only a few thousand dollars have been spent for the study of the nature and cause of these conditions and the proper treatment for these persons. Through the Bureau of Juvenile Research complete mental and physical examination should be made of all juvenile offenders committed to a state institution, appearing before the juvenile court or those school children three or more years retarded and not making satisfactory adjustment to the school environment. Ultimately adult offenders committed to state institutions or those appearing before criminal courts, where mental deficiency is suspected, should be examined. Certainly the greatest success in probation and parole work is not possible until the fundamental aspects and factors of each individual case are known and the decision as to the time

and conditions of probation and parole made with reference to these facts.

The state insane hospitals are not abreast with the times. The medical work is entirely inadequate and the research and investigation neglected. Real preventive work has not been started. The prompt recognition and correction of medical and surgical diseases, co-existent with disordered mental states, would undoubtedly entirely clear up many early cases and improve others sufficiently to permit their early discharge from the institutions.

This preventive work can be done by the establishment of mental clinics where persons in the early stages of insanity can receive advice and treatment, by the employment of field workers to discover incipient cases, to supervise discharged patients, and by other methods.

Chronic insane patients who are in good physical condition and who require long continued care should be segregated and housed in suitable buildings and be employed in farming, dairying, and gardening work. This would permit the concentration of medical and nursing efforts on curable cases, and would mark definite improvement over the present system.

Each hospital should have a consulting staff of leading specialists. Every patient who enters a hospital should be given a thorough mental and medical examination and all defects or disorders should be promptly corrected and treated. The Cleveland hospital, it is suggested, could be used as a reception hospital, acute medical and surgical hospital, diagnostic clinic, laboratories and an infirmary for terminal cases. It would be the clearing house for insane patients from that section of the state.

The Board estimates that there are 21,000 feeble-minded persons in the state of which number 10,000 need institutional care. The state has provision, however, for 3,000. Those who are physically able should be employed at some productive work. Prisoners, for instance, should be used on public work. The argument that the employment of three or four thousand persons in various occupations in the penal institutions would have any appreciable effect on the stability of any industry in the state seems absurd.

It is recommended that three commissions to study and report on the special problems of public welfare be appointed to study penal institutions, the problem of the blind, and to consider the purchase of Longview Hospital.

**THE MILK PROBLEM  
IN SCHOOLS**

It is important in serving milk to young and growing children and youths to give the proper percentage of butterfats in each and every glass served.

This cannot be done when milk is served by the old style dipper, pitcher or tank method. With such service some get the cream and others get the skim milk.

**THE  
LYONS SANITARY  
MILK URN**

is the accepted method of modern milk service. With this urn each and every glass of milk that is drawn contains the same and proper percentage of butter fat. This is accomplished by a simple but effective float tube which draws off exactly the right proportion of "top milk" for each glass, without mixing or agitating mechanism.

It makes no difference whether the milk remains in the urn 2 minutes or 24 hours. All you need to do is place the day's supply of milk into the urn and draw it out through the faucet as you need it.

The Lyon's Urn is easily cleaned, and thoroughly sanitary. The insulated walls maintain exactly the right temperature. The milk will always be sweet, clean, cold and fresh.

Another striking feature of the Lyons Urn is that the cover and faucet can be locked after each meal.

**LYONS SANITARY URN CO.**

235 East 44th Street New York City

The Lyons Sanitary Milk Urn is unexcelled for use in school and industrial cafeterias, diet kitchens, mess halls, Hospital Wards, Institutions, and for general service.

# Child Labor and Mental Hygiene

THE popular conception of child labor is limited very largely to its physical and physiological aspects. Due emphasis has not been made on the psychical side of the child labor experience. Deformation of the person is not more terrible than deformation of the personality, and the life of the body is not to be more esteemed than the life of the mind, as is pointed out by Raymond G. Fuller in the *American Child* of May, 1921. The child has a mind, a nervous system, a body physically immature, susceptible, and plastic.

The nervous disorders and derangements in which child labor may be a contributing factor range from slight abnormalities to functional diseases, in which the power of sight, or the use of the arms or legs have been lost. Chorea *dementia praecox* have their roots in the functional disorders of childhood and youth. Most of the childhood laborers are in the period of early adolescence when neurotic disturbances are peculiarly liable to appear and become deep seated. The time of prevention is childhood, and little consideration is given to the tragedy and cause of preventable nervous diseases.

Play as a spontaneous and self-expressing activity, is always according to nature. It conforms at every moment of the child's life to the genetics of his growth and development. It reflects the various instinctive tendencies, helping to ripen and strengthen it. In short it obeys the self-finding and self-developing push within the child. On the negative side it respects the limitations of the child as regards these neuromuscular coordinations and psychic motives.

Child labor in many of its forms constitutes a repressive environment. It is no respecter of instinctive needs and may lead directly to nervous disturbance and disorders as well as indirectly through the fatigue it occasions. Queer complexes are built up, manifesting themselves in queer behavior.

The psychical side of the child labor evil may be stated in terms of suggestibility. In child labor there is a combination of two factors, suggestibility and fatigue. These may become psychopathic, with consequences serious in their extent. It is incontrovertible that there would be less mental ill health and inefficiency in adults today if there had been less child labor and more childhood play.

The enormous child labor turnover is self-explanatory. The instincts, interests and desires, such as those of initiative, constructiveness, curiosity, thwarted it may have been in school, are likely to be thwarted again in child labor. There is disappointment and disillusion, with usually no counsel to mitigate the shock or help the child to adjust himself to the new conditions. One job after another is tried in the search for satisfaction and self expression. There is intermittent work and idleness with little gained in the way of vocational training or of helpful discipline. Habits of vacillation, of change, and of failure are formed, leaving their mark in weakened will and character.

As the author points out, not the cities, nor the city streets, nor yet the factories are the true homes of childhood, but rather the fields and forests, the rivers and hills and the shores of the sea. The city is a false environment, with its manifold noises, its rhythms false to nature. So far as possible they must live the simple life and the life of play. The stress and strain of urban life must be mitigated, but even in country places, in the great outdoors children are growing up in conditions not in keeping with their needs and the demands of their natures. Play is a safety valve for overflowing energy and spirits and motor expression through play of the highest educational value. He thus discovers himself slowly, achieves command of his powers, and makes full use of his opportunities.

## What Health Service Costs

A study of the cost of health service in industry made by the National Industrial Conference Board, shows that the average for the industries reporting is \$4.43 per employee per year, says the *Monthly Labor Review*. The lowest cost reported was \$1.84 per employee per year in the tobacco industry, and the highest was \$24.40 in the mining industry.

The information was gathered by means of questionnaires submitted to manufacturing plants in representative industrial communities throughout the country. Of the replies received 207 contained complete information that could be used in the analysis. One hundred four of the replies were based on the records of 1919, 99 on records of 1920, and 4 on records of 1918. In the plants reporting, 764,827 workers were employed, of whom 631,582 were males, and 133,254 were females. The number of workers per plant varied from 129 to 33,960.

The information received discloses that the earliest recorded effort on the part of the management to conserve workers' health was made in 1879. Only 9 of the firms reporting had health supervision previous to 1900, while 164, or 86.7 per cent, established health service in 1910 or later. The largest number introduced it in 1916, and the next largest in 1919. The following table, prepared by the National Industrial Conference Board, shows at a glance the cost of industrial medical departments for the various industries reporting.

Industry	No. Plants Reporting	Number of Workers			Total Cost	Cost per Person
		Male	Female	Total		
Abrasive .....	5	7,613	612	8,225	\$ 64,810	\$ 7.88

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

*Made only by*

## Plant Disability Funds

THE most recent report by the New York State Industrial Commission is a bulletin on Plant Disability Funds, April, 1921. Forty-one funds were analyzed in response to various requests for information regarding the installation of Disability Funds. The study was confined to funds either jointly supported by management and employees or supported solely by employees. No plants were neglected which supported or administered solely by the management. The funds were taken from thirty-four different industries and approximately 228,000 employees were represented.

The report discusses the type of funds, the maintenance and administration of the funds, the qualifications for membership, the medical service, the waiting period, benefits and costs.

The report, while superficial, will prove suggestive to employers and organizations contemplating the establishment of Disability Funds. Six processes for the administration of such funds, and suggested as having been borne out by experience shown in this investigation.

(1) The plan should be sold to management and men alike. The underlying purpose should permeate the organization from the top down and the bottom up. Superimposed plans are doomed to failure.

(2) The plan should be democratic. As far as possible, the employees should have the fullest possible participation in the organization. However, the presence of management in the form of a company secretary or treasurer is often indispensable and promotes greater efficiency. Joint boards of directors with round-table discussions are generally successful.

(3) Jointly supported funds are found more universally practical than organizations run entirely by management or men. A far larger proportion of employees join such funds rather than associations run entirely by employees. The employee feels he has a real share in an organization whose interests will be efficiently guarded, and at the same time feels no restraint in using the accrued benefits, as he does in a paternalistic or "hand down" fund, run entirely by management.

(4) Certain restrictions on membership maintain organizations up to high standards. Proper physical examinations keep funds free from malingerers. Age provisions should seek to place the burden of risk upon the whole, and not simply the responsibility of the aged upon the young. A short probationary period of membership gives an increased value of the benefit to the members, and helps eliminate floaters. Without at least these provisions, employees have little interest in such organizations.

(5) Adequate medical service should be provided. A plant disability fund should aim not only at relief, but at safeguarding the health of the employees. There should be an earnest attempt to reduce the frequency of and severity of sickness by good medical advice and periodic examination given in the spirit of helpfulness. Few funds give adequate medical care to the disabled. In many funds, the employee chooses and pays for his own doctor. While such a plan eliminates paternalism, in many cases it results in the employee failing to have proper medical attention in time of real need. Many associations, conducted under jointly supported plans, elect their own doctors. Such a scheme would seem democratic, yet fairly efficient.

(6) Dues rates should be related to prevailing wage rates so that membership may be within reach of all classes of employees. Benefit rates should render adequate compensation; they should be neither too low nor too high so as to cause prohibition of the use of benefits on the one hand or malingering on the other; they should seek to satisfy the greater need as the length of sickness increases. Faithful employees, upon death after a long term of service, would seem worthy of more than a small funeral benefit.

### Modern Beds Unhealthy, Says London Doctor

That the sort of bed one sleeps in has a profound influence on health and posture is pointed out by the medical correspondent of the *London Times*. Although a man spends one third of his life in bed, he takes his sleeping accommodations as a matter of course. The importance of a comfortable bed cannot be over-emphasized since it is the great place of human recuperation. There the cells of the brain are recharged; the elimination of poison and rebuilding of worn-out tissue are carried on.

The modern bed consisting of a wire mattress on which a hair mattress is superimposed does not admit of true relaxation. Such a bed does not shape itself about the body, and with the sinking of the wire mattress, the sleeper is forced to suffer double discomfort, he sinks down in the bed and his back is twisted.

Persons in good health do not notice the discomfort of their beds until sleeplessness or illness overtake them. The middle-aged man who is at the height of his working life always pays the heaviest penalty. The modern bed does not allow his muscles to relax. His rigidity keeps him awake and he becomes a victim of insomnia.

Water beds, pneumatic beds, and rubber beds are recommended as healthful and comfortable. Such a bed would mold itself to the sleeper's form and the backbone would be maintained straight.

The proper ventilation of the bedroom is also urged by the physician. In summertime it is as necessary to comfort to keep the bedroom cooled by an electric fan as it is to have the room not too chilled in winter. The practice of opening wide the windows and then piling on huge piles of heavy blankets is encraving and exhausting to the sleeper.

The question of high or low pillows is one of individual preference, the doctor states, though one too soft is to be avoided as well as the round bolster. Pillows now used are likewise uncomfortable and need improvement.

### Belgium Draws Up Physical Education Platform

A special government commission in Belgium recommends the following physical education reforms:

Compulsory physical training for boys and girls in all elementary and high schools, including industrial and special schools; continuance of physical training up to the age of 18, by children who have been permitted to leave school; a permanent government council on physical education and a bureau for the administration of the law bearing on the subject.

### Negro Infant Mortality Rate Lowered in New York

The infant mortality rate among the colored population of New York City is almost twice that among the whites. As a result of the intensive campaign carried on since 1915, the rates have been lowered from 96.2 for the white infants and 202 for the colored, to 83 for the white and 164 for the colored. The white rate was reduced 13 per cent and the colored 18 per cent. The reduction of the rate among the Negro population is not only a tribute to the efforts of the Bureau of Child Hygiene and the various child caring organizations operating in the districts concerned, but it is also a sign of an awakening on the part of the colored population to the importance of life-saving measures among its children, and a more ready response to the educational propaganda put forth in their behalf.

The Dermatological Research Laboratories were first in the United States to produce Arsphenamine.—Due to the systematic efforts of our research staff, with laboratory facilities and personnel adapted to intensive concentration largely in this particular field, we are now producing a

## NEO ARSPHENAMINE

of such low toxicity and high therapeutic effect that it may be regarded as a super neo arsphenamine.

For the convenience of physicians who have not ready access to reliably distilled sterile water, we supply a bulk package (illustrated) containing 10 ampoules of any one dosage of neo arsphenamine with 10 ampoules of chemically pure sterile water (free from organic matter.) Solution may be effected in the ampoule and syringe.

## Readings in Evolution, Genetics and Eugenics

The University of Chicago has brought out in Horatio Hackett Newman's book under the above title another volume of inestimable value to the man who needs must keep abreast of progress and yet whose time does not permit unlimited research into the literature of science, or whose earlier training has lacked authoritative direction. Newman has presented the various phases of evolutionary biology in their ordered sequence. The rise of the concept, the evidence, the cause-mechanical theories of evolution, the problems of genetics and eugenics as applied to human improvement—all are adequately and interestingly handled. In a masterly manner coherence is given by the author to the panoramic view of human life as unrolled by successive workers. The choicest of paragraphs from classical evolutionary and modern writers have been chosen to tell the biologic story.

The chapters concerned with the mechanism of heredity are non-technical and are particularly clear in their bearing on applied genetics. Would-be improvers of types and indeed the people generally would do well to con them carefully in the interest of achieving a rational attitude toward the business of living and in evaluating the measures man proposes to substitute for processes of natural selection.

The conservation of the highest human characteristics considers, along with the biologic necessity of being well born, the utmost of educational endeavor and environmental influence to foster favorable heritage. An educated sentiment in racial matters is a fundamental necessity since in the popular mind actual knowledge is so generally confused with a mass of tradition and opinion. Society must learn to protect itself against repetitions of hereditary blunders. Predictability of human types is not to be looked for. Says Saleeby: "We could not undertake to produce a Shakespeare, but we might reasonably hope to produce a generation which would not destroy its Shakespeares."

A rational consideration of racial attitudes toward racial problems but serves to emphasize the unintelligence with which they are countered. The struggle toward racial perfection lies in the way of eugenics, that is, the wastage of children is to be avoided by the elevation of parenthood; unemployment is countered by limiting the

propagation of those types whom unfavorable inheritance marks from the first as fundamentally incompetent and unemployable. Especially should we assess highly and foster the types who evince mental energy or that capacity for labor which is so closely allied to mental achievement. "The land is overstocked," Galton is quoted as saying, "with the listless and incapable. In any scheme of eugenics energy is the most important quality to favor; it is the basis of living action, and is eminently transmissible by descent." Eugenics can reasonably promise, when its principles are recognized, to multiply the human and diminish the vegetable types in the community.

University of Chicago Press, 1921.

## The Problems of Industrial Government

The problems of industry both from an economic and political point of view have occupied much attention and comment. The publication of "Industrial government" by John R. Commons and others it is to be hoped may clarify some of the current ideas and organize some of the enterprising practices developing. The present book is a study of some thirty establishments visited during 1919 and whose experience extended beyond the immediate period of the war distinguished perhaps by a system of organization or by a dominating personality which evolved its own system. New and temporary experiments are not included.

The plants whose work is outlined, are for the most part entirely familiar to even the casual student of governmental or industry. Ford, Filene, Link-Belt, Joseph & Feiss, Dennison, and others are presented for scrutiny. New anecdotes are told, figures quoted, motives analyzed. Faith in profits, in management, in workers, hope for the future, the groping for justice, for regular employment and profit sharing, the regard or disregard for association or unionism, the striving for efficiency, the struggle for life, all find a place in the tilt. Different men with different ideas and hopes trot out their cures but the last word can scarcely be said yet. Inferences but not conclusions are drawn. There are similarities and differences in each system but it would seem that the seeds future correlation might be available.

The possession of a power to bargain is of course the *sine qua non* in the development of industrial law.

The use and abuse of this power is a very fascinating thing, sometimes hopeful, sometimes not so much so. As in the Hart, Schaffner & Marx arrangement, the workers are assured of equal power with the management, their representatives are responsible, their judges are impartial as judges can be.

In the inferences drawn by the authors various phases or needs are emphasized as of importance; security of job, management (including human relationships and contacts as well as a new leadership of active managerial vision and capacity); the representation of employees and joint contract. These are admittedly factors of fundamental importance. These same struggles and ideas have occupied the attention of men in the Church, in politics, and in industry. The struggles of the Church and State ended in the development of modern democracy, the extension of suffrage, of education, and the idea of public welfare. Does the struggle in industry differ? At the time the Church occupied the forefront, religious ideas and theological discussions occupied the attention of human thought, reaching down to the very foundation of reasoning and relationships. Then the State rose to assert its power. Has our Democracy been politically successful? Have we really attained our hopes? Some turn away perhaps with disgust saying that in industry and industrial activities the solution will be found. Certainly contributions and suggestions are being made, but on the whole one is reminded of the old feudastic struggles for power with the bitter controversies resolving finally into the concept of a finer, higher, community of power and spirit.

Macmillan Company, New York, 1921.

## Bright's Disease Decreases

The experience of the Metropolitan Life Insurance Company in losses from Bright's disease indicates a reduction of 30 per cent in the death rate since 1916 as reported in the *Statistical Bulletin*. According to the life tables compiled by the company the average life span of each individual would be increased from one year to a year and one quarter if Bright's disease were entirely eliminated. A campaign for more careful personal hygiene, diminished use of alcoholic beverages, and wider extension of periodical medical examinations will be responsible for a further decrease in mortality from the disease.

## Radiant Heat vs. Convective Heat

In industrial as well as private practice there is frequent need for the application of heat, particularly in such cases as neuralgia, neuritis, sciatica, mastoiditis and rheumatism.

The common practice was to employ some form of convective heat such as poultices, hot-water bottles, jacks, etc.

Today the profession recognizes the greater benefits derived from Radiant Heat, particularly as exemplified in

## The New Thermolite

This new method of heat application insures deeper penetration, resulting in a marked hyperemia, with a decided sedative and analgesic effect derived from reflex action on the peripheral nerve endings.

The new Thermolite radiates only parallel rays, with no focal point to cause burning.

The outer twelve-inch aluminum reflector contains a highly polished parabolic projector which in conjunction with a special 375 watt 120 volt lamp furnishes a parallel penetrating beam of correct intensity that covers an area of about 300 square inches at operating distance (36 inches from reflector).

*A booklet illustrating The Thermolite in more detail will be sent free upon request.*

## CASE RECORD FORMS

### Keeping Up to Date

THE System of Hospital Case Record Forms devised by the American College of Surgeons has been in use in many hospitals for upwards of two years. From time to time new forms have been added as experience has shown the need. The College has issued a new bulletin covering these additions which has been mailed to all hospitals.

The Faithorn Company supplies these forms, well printed, on durable bond paper, at favorable rates. All new forms are added and revisions made as they are developed by the College. Rates on new forms are the same as given on other forms in our catalog.

*Please note*—We prepay all shipments, thus distance is no barrier to buying of us, and you receive the forms with no more inconvenience than if ordered locally.

### Filing Devices

Next in importance to the keeping of accurate case records is an adequate system of filing. We supply loose-leaf binders for temporary filing, and filing cases with indexes for permanent file.

*If you have not received our catalog and price list, we will be pleased to send upon request*

## New Views on Vitamines

A NEW book under the caption, "The Vitamine Manual," by Walter H. Eddy, associate professor of physiological chemistry, Teachers College, Columbia University, brings into the compass of one small volume, a comprehensive but very readable account of recent nutritional studies, particularly with reference to certain elusive accessory food factors called vitamines, but which are probably misnamed, have never been fully identified, and really have no chemical identity. Research work of the greatest complexity has set itself the task of solving the problems they present. Meanwhile, the data in hand have compelled us to reform our ideas of nutrition of both adults and infants, and to pick out our food from a new angle.

Guess work in the choice of foods is as much out of date as, other games of chance with the cards stacked against one. A great advance was made in the determination of food values with the discovery of the fact that food is to the human motor what fuel is to the engine, and that food eaten liberates in the body practically the same amount of energy it would produce if it were burned in oxygen outside the body. This isodynamic law made it possible to measure the value of a given food in caloric units. It remained only to estimate the caloric needs of men and women in different occupations in order to devise a proper ration for every type of worker.

It was soon discovered, however, that to preserve the nutritional balance is not so simple a matter as merely giving food fuel to the body furnace. While chemical analysis has proved the many varieties of foodstuffs to be chemically combinations of pure compounds of relatively few varieties, even slight variations in quantities or proportions of the necessary constituents cause changes in function. Malnutrition at critical developmental periods modifies types, and the widespread shortage of certain food factors may produce obscure and far reaching diseases among the people.

The investigation of such deficiency diseases resulted in the discovery that the mere caloric concept of food values is inadequate, that diets otherwise meeting all requirements fail in the absence of the vitamines, which are known to be of three types: A, B and C, and that no dietary is ration-

ally planned which does not take into account these accessory factors.

The book in question is useful in the hands of the lay public if only for the tables, one from the Report of the British Medical Research Committee, and a second table compiled from a review of both British and American data, representing a rather more complete classification than the British report, which give vitamine values in all the available foods.

Nor is it safe to assume that all foods supposedly adequate in this regard are uniformly high in vitamine content. It is known that milk, for instance, is merely a mobilization of the vitamines eaten. Cows on winter feeds may produce milk low in vitamines. Also, the food prejudices of a lactating mother—especially if

directed against green vegetables—may jeopardize the health of her babe. Or the necessary pasteurization of milk may lower the vitamine content and require to be compensated for by the addition of fruit or vegetable juices to the diet.

The inevitable lesson to be drawn from the benefits so generally reported from the ingestion of yeast is that the tendency of the adult population to confine their foods to meat, potato, and cereal results in a vitamine shortage which calls for salads and dairy products as features of the every day meal.

The correction of these ills is to be found in the intelligent selection of the diet, which is better far than persistent dependence on medicinal correctives. Nature is a better chemist than man and has a much better knowledge than the chemist of what are our dietary needs.

Williams & Wilkins Co., Baltimore, 1921.

## Our Social Heritage

THE relation of the individual to his government and the opportunities for his development have been the occasion of much discussion and comment. Graham Wallas is of course a well known author both in the field of politics and of sociology, or perhaps more exactly, the field of social control. His earlier books, "Human Nature in Politics" and later "The Great Society" have done much to focus attention on some of the problems of government. A recent book "Our Social Heritage" continues the analysis entering somewhat more the field of nationalism and internationalism.

Our heritage is in fact twofold. Our nature is our biological inheritance or physical structure. Our nurture consists of that which each acquires for himself, and the knowledge, expedients, and habits, originally the personal acquisition of individuals but now developed through the social process of teaching and learning. This is termed "Our Social Heritage."

We are in fact increasingly dependent on our social heritage, or as Mr. Wallas says "biologically parasitic." Although man has evolved and is still evolving certain modifications of structure and instinct. These increase his power of acquiring and using his social heritage just as they increase his dependence upon it. Through an analysis of individual co-

operation we study the cooperation of groups which in fact requires a combination of socially inherited with biologically inherited instincts. Our socially inherited instincts are imperfectly worked out and are apt to break down at various points and their place taken by the primitive instinctive process. As the experiences of war and diplomacy show, we are untrained for cooperative thought for which the most necessary rule is absolute frankness among the cooperative thinkers. The chief need is to evolve new forms of cooperative processes as men cannot exist in their present numbers on the earth without world cooperation to foster everything which helps to connect cause and effect in long range actions.

In the concluding chapters are analyzed the two forms of thought and action which are to make the good life possible for all mankind, science with its general conception of cause and effect, and the tradition embodied in the church. One turns from the book with the conviction that "the special task of our generation might be so to work and think as to be able to hand on to the boys and girls who fifty years hence at some turning point of world history may gather in the schools, the heritage of a world-outlook deeper and wider and more helpful than that of modern Christendom."

Yale University Press, New Haven, 1921.

# Unguentine

An ideal surgical dressing for the treatment of burns, wounds, chronic ulcers and any abrasions of the skin or mucous membrane. It has an antiphlogistic, mildly astringent, antiseptic and stimulating action.

This is demonstrated by the almost immediate relief from pain when applied to an injury, the prevention of mild and restriction of acute infection, formation of healthy epithelial tissue from the edges of the wound, and the healing of chronic ulcers.

## Psychology and Psychotherapy

This book by William Brown concerns itself with those borderline nervous reactions known as hysteria, neurasthenia, psychoasthenia, and the compulsion neuroses, in which he sees a purely psychogenic origin and commends psycho-therapeutic measures. While antecedent disharmonies or emotional preoccupations of long standing were noted in some of his cases, in his war experience the recent shock or stress of war experience was the major factor. His method consists in a modified hypnotism and suggestion. Mental analysis was found helpful. The success of the method hinged largely upon seeing the cases early.

Different schools of thought, says Brown, tend to emphasize one or another factor of cure. Psychotherapy should take account of them all. He, therefore, discusses and brings into contrast the views of Freud as against Ribot, McDougall, and Shand. The views of Freud, he says, are rather vague and incomplete and "also suffer from lack of historical relationship with the work of expert psychologists." He expresses himself as an adherent to Bergson's theory of memory and of the relation of mind to brain. In his chapter on hypnotism and psychical research he sounds a note of warning that in the results of scientific investigation into spiritism it must be made quite certain that the mind concerned is a normal one, as the whole subject borders very closely on the realm of pathological psychology.

Edward Arnold, London, 1921.

## The Genuine Works of Hippocrates

The position of the Greek in virtually all fields of thought, his pre-eminence among idealists and philosophers of succeeding ages, can scarcely be challenged. During his period there arose in the field of medicine, as of art, politics, etc., a gradual distinction between the ethics in medicine or the ethics in politics. The two up to this time had been indistinguishable and for the first time a separation was inaugurated. The distinction was not sharply defined as yet and mysticism still clung to a certain extent, but by the time of Hippocrates there had arisen a very definite trend away from the more or less haphazard or empirical methods to an ever increasing emphasis upon the institutionalization of medicine and exactness of method. In

other words, there arose not only a more or less distinct technic, but, what is equally important, the custom of recording their practices—what we now call record taking or bedside notes. In all probability, for the most part at least, Hippocrates may have reflected or merely accumulated the spirit and practice of his time, but he has remained an outstanding figure in the chronicles of medicine.

The dates of his birth and death are uncertain. It is generally agreed, however, that he lived the latter part of the Fifth Century B. C. He numbered among his contemporaries of this perhaps most brilliant intellectual period of the human race Pericles, Aeschylus, Sophocles, Euripedes, Socrates, Plato, Xenophen, Herodotus, and numerous others whose work stands, towering alone above the accomplishments of other men, even despite the disparity of time and place.

It is impossible here to enumerate the steps in the history of medicine. Suffice it to say that the consensus of opinion seems to have designated Hippocrates as the originator of a system of medicine bearing his name and characterized by its emphasis on record taking and prognosis, close observation and deduction,—on the substitution of experience for empiricism. Much of his work has been lost and much that remains has been superseded, but the virility and charm remains intact.

The present book by Francis Adams gives at length the philosophy and knowledge of the time, the authenticity of the works quoted, with a translation and comment upon works generally conceded to be those of Hippocrates: On Ancient Medicine; On Surgery; Law; On Ulcers; etc.

William Wood & Co., New York, 1921.

## Women Professional Workers

The woman as a professional worker has been the subject of an investigation by Dr. Elizabeth Kemper Adams for the Women's Educational and Industrial Union. A comment on her position as a professional worker brings, first of all, an analysis of terms, of requirements and recompenses. The author has gathered some very interesting data concerning requirements which are quite generally known and remuneration which are not so well known. During 1918-1919 some eighteen lawyers filed schedules, nine in independent positions, eight in salaried positions, one dean of her own law school. In the independent groups was listed

one who was her own father's partner, one her husband's partner, one an editor of a law journal, etc. The salary schedule seems to range from \$600 to \$5,000 with a median of \$1,800 to \$2,000. Medical women range from \$1,200 and maintenance (about \$1,700 in all) to \$5,000, with a median salary of \$2,600, while in the ministerial field only three salaries are reported ranging from \$720 to \$2,100; medical social workers \$1,500 to \$2,600 with a median of \$1,800; psychiatric workers \$960 to \$1,500, median \$1,160.

It is impossible here to go down the list of services enumerated, and certain it is that the remuneration alone is not the determinant for either men or women, and yet the maximum here seems to become a minimum elsewhere. If one is for a period of years to devote one's life, hope and ambition, not only the samaritan but the pecuniary idea has its place.

The author has gathered some valuable material and given an impartial presentation of data. The professional woman is here probably to stay; her difficulties and disappointments are not new, but with careful thought and organized effort much of the unpleasantness and hard feeling of the past can be done away with. "But whether she continues her professional work actively or not, the modern woman with professional training and experience is bound to make them felt for the public good, in the home and the community."

Macmillan Company, New York, 1921.

## The American Dollar and "AMERICAN" Sterilizers

An advertisement worth the reading of any interested in the purchase of sterilizing equipment—and directed particularly to those seeking the most for their expenditure.

WITH all eyes centered upon Price, the purchasing power of the American dollar has never been so taxed as it is today.

We sense that you are not immune to the price appeal in the purchase of your equipment. You are seeking the very most your money will buy—and rightly so. It is, therefore, a source of keen satisfaction to us to know and be able to prove that

**AMERICAN**  
THE PRODUCT OF SPECIALISTS  
**AMERICAN**  
Sterilizers and Disinfectors

at present prices represent the greatest Sterilizer and Disinfectant value obtainable. Notwithstanding the fact that they cost more to manufacture, due to the use of finer materials, more searching tests, more scientific and precise shop and machine work, more exacting inspection, and are consequently worth far more to the owner, they are sold today for less per unit of value than any similar apparatus made. Greater skill, greater specialization, greater achievement do not make the "AMERICAN" cost more—they do make it worth more.

And the purchase price, low as it is, is greatly lessened in the after years of uninterrupted service because of low maintenance and operating costs. Your dollar has been creditably spent when it goes for "AMERICAN" apparatus.

Descriptive bulletins, engineering data and specialists' counsel are free for the asking.

New York Office:  
Fifth Avenue Building,  
200 Fifth Avenue

## Maternal Mortality in New York City

A total of maternal death rates from all causes connected with the puerperal state, based on 10,000 labors (live and still births) for the years 1915 to 1919, is given as follows for certain American cities and two European cities where the data were available: New York City, 46.11; Philadelphia, 61.48; Baltimore, 64.89; Boston, 70.71; Stockholm (Sweden), 40.42; and Birmingham (England), 33.49. The average total rate for all diseases connected with the puerperal state in New York City, 46.11 for 10,000 labors, is conspicuously lower than that for any other city in the United States under consideration. It is, however, 35 per cent higher than Birmingham. The average rate for puerperal septicemia is not only lower than that for Birmingham, but the rate for this infection has fallen considerably throughout the five-year period, and in 1919 reached 11.41 for ten thousand labors. It is estimated that the registration area of the United States for 1918 contained 53 per cent of the population of the United States and some of the largest cities of the Atlantic Coast and Great Lakes region, excluding Chicago.

In discussing the analyses of the death rate, William Travis Howard, Jr., of Johns Hopkins University, writing in the *American Journal of Hygiene*, May, 1921, points out that the death rate, whether viewed in comparison with the death rates for England or Wales or considered alone are exceedingly high. To match the rate for the whole puerperal state, 88.48 per 10,000 births, it is necessary to revert to the Swedish rate of 1806 to 1810 (89 per 10,000 deaths). It is more than double the Swedish rate for 1851 to 1855, 75 per cent more

than the average rate for England and Wales for 1847 to 1876 (50 per 10,000 living births) and 120 per cent greater than the average rate for the latter area for 1911 to 1915 (40.31 per 10,000 living births), although an allowance for still births was made.

The reduction of maternal death rates is due in a large part to the administrative measures brought about by the better protection of women during the puerperal period, and the raising of the standards of obstetrics by midwives. Measures of this kind have been carried out in New York the last twelve years and by the Department of Health and considered to be essential in any well-rounded public health program. Control of the practice of midwifery includes refusal of issuing a license to any midwife who had not practiced in the city prior to 1907 unless she is a graduate of the Bellevue Hospital School for midwives which is maintained by the City of New York and has an eight months course of instruction, or unless she is a graduate of an accredited European school of equal or higher standing.

The Bureau of Child Hygiene, in addition to this, carries on a systematic and widespread supervision of the practice of these women, who at the present time report about 37 per cent of all births.

In the period of years, 1914 to 1918 inclusive, among mothers who have received the advantages of pre-natal care, the percentage of maternal deaths during the period of pregnancy was .24 as compared with .45 for the city as a whole, a reduction of about 50 per cent, while the death rate under one month of age per thousand babies born to mothers under pre-natal supervision was 17.7 as compared with 36.3 for the same type of babies in the city as a whole.

again a reduction of over 50 per cent. What New York has accomplished is entirely possible for any community.

## Common Cups Illegal in Forty-One States

Forty-one states in the Union have abolished the use of the common drinking cup in all public places by state laws or regulations of the state boards of health. At the time of the compilation of a report, December, 1920, the following states had no legislation prohibiting the use of the common drinking cup: Georgia, South Carolina, North Carolina, Iowa, Texas, Nevada, Washington, and Wyoming. There are no laws in Canada preventing the use of the common cup though paper cups are generally used in cities.

## Offer International Hygiene Diploma

Three European Universities, in England, France and Switzerland, respectively, are for the first time this year conducting courses leading to an international diploma in hygiene. The University of Cambridge, the University of Paris, and the University of Zurich are conducting the courses which are open to physicians from other lands.

## Call World Congress of Anesthetists

The first world's gathering of anesthetists will be held in October, 1922, when the World's Congress of Anesthetists meets at Columbus, O. Invitations have been extended to leading members of the profession in London, Paris, Vienna, Buenos Aires and Sydney. The World Congress will be held in conjunction with the next annual meeting of the National Anesthesia Research Society.

# NURSES PLACED IN HOSPITALS

# HOSPITALS SUPPLIED WITH NURSES

**A**ZNOES' is a specialized service that introduces the nurse, dietitian, or industrial physician to the position for which they are best fitted. By the same token the right individual is secured for any opening in hospital, health or industrial medical service.

Our Booklet "Finding the Nurse and Finding the Position" will be of interest to both those having open positions and those seeking employment.

**Central Registry  
for Nurses**

30 N. Michigan Ave., Chicago

The National Physicians Exchange is that part of our service which specializes in bringing physicians in touch with hospitals, industrial plants, etc., having suitable openings.

# The Application of Radiant Heat

**The Bier Therapeutic Lamp**

This is one of the larger types of therapeutic lamps. Furnished either on independent floor stand or wall bracket as desired. It is equipped with 1,000-watt Mazda Tungsten filament globe which delivers approximately 2,000 candle power. Ready adjustability is insured by an improved tilting device which changes the angle of application. A counter-balanced weight permits the lamp to be raised or lowered with ease.

The Bier lamp consumes 10 amperes of current and the circuit should be fused accordingly.

Much of the value of this appliance rests in the scientifically designed reflector which projects the maximum amount of light and heat rays without distortion.

- 9NH2397 Bier Therapeutic Lamp on floor stand \$65.00
- 9NH2396 Bier Therapeutic Lamp on wall bracket with 5' extension arm..... 45.00
- 9NH2457 14" Screens, ruby, amber, blue or violet ..... 6.50

The therapeutic value of radiant light and heat is thoroughly recognized by the profession. In addition to certain remedial values, the use of therapeutic lamps is indicated because of marked sedative and anodyne effects.

The equipment of every industrial first aid station, clinic or dispensary should include apparatus permitting the scientific application of radiant heat.

The two appliances shown herewith will meet the requirements of many surgeons. Full detailed information and catalog sent on request.

**Betz Therapeutic Hand Lamp**

A very popular portable type, furnished complete with polished aluminum reflector, thoroughly ventilated to prevent overheating. All color globes furnished with this equipment are blown in the glass and are not dipped or treated.

- 9NH2489 Hand Therapeutic Lamp with 75-watt 200 C. P., pear shaped nitrogen filled crystal globe ..... \$6.50
  - 9NH2490 Same, with 50 C. P., 200-watt crystal globe ..... 7.50
  - 9NH2491 Same, with 50 C. P., 200-watt round violet globe ..... 8.50
  - 9NH2492 Same, with one each 50 C. P., 200-watt violet, ruby and crystal globes..... 14.00
  - 9NH2493 Round violet 50 C. P., 200-watt globe only ..... 3.50
  - 9NH2494 Same as above, only crystal..... 2.25
  - 9NH2495 Same as above, only ruby ..... 3.50
  - 9NH2496 Same as above, only amber ..... 3.50
- Above globes are all carbon filament.
- 9NH2430 Pear shaped, 200 C. P., 75-watt nitrogen-filled crystal globe only ..... .80
  - 9NH2455 5-inch Screens, ruby, amber, blue or violet ..... 3.25

## Illinois Seeks to Increase Birth Registration

In order to attain the 90 per cent birth registration, the figure required for admittance into the national Registration Area and in compliance with a resolution passed by the Illinois Board of Public Health Advisors, Dr. I. D. Rawlings, State Director of Public Health, has sent letters to every physician and mid-wife practicing in Illinois urging the registration of births.

A law providing for the registration of all births, still births and deaths was passed by the Illinois General Assembly to take effect July 1, 1915. For lack of appropriations it did not become effective until January 1, 1916. Though this law provides that "it shall be the duty of the attending physician or midwife to file a certificate of birth. . . . with the local registrar of the district in which the birth occurred within ten days after the date of birth," only 82 per cent of the births in Illinois have been registered.

The letter urges that the report of such births be sent in immediately so that when the United States government checks the registration of births in Illinois for 1921 the number

found registered will be sufficient to admit Illinois to the Registration Area.

## Dietitians Needed in Public Health Service

The United States Civil Service Commission states that there is need for a considerable number of dietitians in the Public Health Service at Hospitals throughout the United States and that until further notice it will receive applications for such positions.

The basic entrance salary offered is \$960 a year with possible promotion to the basic pay of \$1,344 a year. To all salaries there is added the increase of \$20 a month granted by Congress. In addition, quarters and subsistence are furnished free by the government.

Applicants are not required to undergo a written examination, but are rated upon the subjects of general education, weighted at 30 per cent, and technical training and experience, weighted at 70 per cent.

Full information and application blanks may be obtained by communicating with the United States Civil Service Commission, Washington, D. C., or with the local board of civil

service examiners at the post office or customhouse in any city.

## University of Iowa Has New Department of Eugenics

A Department of Eugenics has been organized by the Child Welfare Station of the University of Iowa to investigate genetic principles and their application to child welfare. Dr. P. W. Whiting has been appointed to have charge of the work.

## Europe Seeks to Safeguard Children Farm Workers

In Europe as in the Western hemisphere there are but few examples of direct legislation bearing upon the labor of children in agriculture. The majority of the European States, have, however, sought a safeguard for children in rural districts through the direct operation of education laws by which the age of a child's admission to general employment can be more or less controlled. Compulsory education, with a school term of sufficient length, supervision to insure that all children of school age are not employed in school hours, and proper certification, should control the situation.

## Quality and Price Are Inseparably Related

It is true economy to buy goods of the finest quality and pay the reasonably higher prices required. They cannot be sold at the prices asked for goods of lower grade.

### ARISTON JELLY POWDERS

Are made of the finest gelatine obtainable—  
Prove it by the wholesome odor when hot water is poured upon the Ariston Powder.

They are flavored with true fruit juices—  
Giving the real flavor which the package label entitles you to expect.

Users of Ariston Gelatine Desserts cannot be satisfied with any of lower grade, and by experience they know that the extra cost for Ariston Quality is small in comparison to the Extra Value in the Ariston Goods.

We cannot be out-bid on quality  
We do not compete on a price basis

Proof of the wisdom of our rigid adherence to high standards is to be found in the fact that our large business with the best institutions of the land is continuously growing.

## ORDER A BINDER FOR THE CURRENT ISSUE OF THE NATION'S HEALTH

In order that subscribers may get the most out of THE NATION'S HEALTH, we suggest the use of our individual copy binders so that the publication can be sent to the various department heads and assistants.

This binder is strongly built and will help preserve your copy while it is being used. It is proof against the magazine's being lost or misplaced. It will insure return to your office for its place in the library.

The maximum benefit from THE NATION'S HEALTH cannot be secured if you alone read the copy. There are articles each month of particular and profitable appeal to everyone connected with your institution.

Our binder is made of heavy binder board, covered with linen cloth. The publication is held in place by a strong, steel spring plate with patented lock.

Send us an order today. The price is \$1.25, plus postage. Send a check, money or express order.

## Smallpox and Typhus Fever in Chile

BY OUR LATIN-AMERICAN CORRESPONDENT

During the past winter (June-July, 1921), small pox made its appearance in Santiago de Chile but did not assume alarming proportions until September, when it was reported that there were over 4,000 cases in that city alone. The Federal and Municipal Governments have put every available measure in force for the control of the epidemic which it is greatly feared will spread to the surrounding provinces. In this work it is much hampered by the lack of hospitals, equipment and supplies. The public press has responded magnificently and is carrying on a campaign of public education, urging their readers to be vaccinated and to cooperate with the health authorities in the enforcement of the sanitary regulations. To make the situation more serious the disease has appeared in Valparaiso and is gaining headway. Typhus fever is prevalent in Santiago and the surrounding provinces. The Minister of the Interior has called a meeting of the sanitary officers at Valparaiso for the purpose of evolving a concerted plan of action for the eradication of the epidemic.

In a speech before the Chilean Senate, Senator Juan Enrique Concha stated that he believed that there are being treated at present at least 10,000 cases of smallpox in Santiago alone, although the total reports for all Chile from January to September, 1921, showed 5,500 cases and 2,500 deaths. Of these cases 2,546 were treated in hospital with 1,147 deaths. In all Chile from October, 1918, to September, 1921, inclusive, there were reported 23,256 cases of typhus of which 5,882 died.

## Cost of Education in United States to be Investigated

An investigation of the cost of education in the United States and the public resources available to support it is to be made by a commission representing the American Council of Education. The expense of the survey will be met by the Commonwealth Fund, the Carnegie Corporation, the General Education Board and the Milbank Memorial Fund. In typical States and communities studies will be made of the existing program of public education, the extent to which this program is carried out and the present and prospective costs involved.

## Dr. McKay New York Child Hygiene Director

Dr. Florence L. McKay has been appointed Director of the Division of Child Hygiene of the State Department of Health, Albany. For the past year, Dr. McKay has been assistant director of the Division of Child Hygiene of the Federal Children's Bureau.

## New Allied Investigations

The physical growth of children from birth to maturity is the subject of the first published study of a series of investigations in the field of child welfare undertaken by the University of Iowa with a view to formulating standards which will establish a basic science for allied investigation in mental, educational, social, and moral development of the child. Clinical studies in nutrition are an important part of the contribution.

The organization of existing human society with a view to its future welfare is the crowning task of the science of man; it needs the keenest minded investigators, the most stringent technic, and the utmost sympathy from all classes of society itself. —Pearson.

**A**RE you making every effort to keep posted on new ideas and more progressive methods of handling your work? Do you apply the results of others to your problems so as to determine whether or not the new way of doing the old things is the best way?

Whether you are a doctor, nurse, surgeon or member of a hospital board, there is but one way to get practical advice and reliable expressions on the very latest and most important hospital and institutional problems and that is through THE MODERN HOSPITAL. There is but one way to get month by month the expressions of the leading men in the field and that is through the dominant publication of the hospital field. ## Federal Aid in Industrial Rehabilitation

By TRACY COPP, SPECIAL AGENT FOR INDUSTRIAL REHABILITATION, FEDERAL BOARD FOR VOCATIONAL EDUCATION, WASHINGTON, D. C.

THE Federal government is offering to finance jointly with the states a plan to place persons handicapped from disease and accident in the way of a better and more remunerative position in life. All but a very few of the states have accepted the offer of the Federal government and before many months have passed the social machinery will begin to function in earnest in the interests of those who are to get a "better chance."

During the last ten years the workers in the industries of the country, with some exceptions, have been compensated for the injuries occurring in the course of their employment. The operation of these laws has become automatic in most cases. Controversies may arise over compensation settlements, though in only a small percentage of them does it actually become serious. Advances have been made in the interests of the workingman, while victims of public disaster and street accidents are left to get justice as the workingman did before the compensation laws were passed.

### The Placement Problem

Compensation for industrial accident may have been intended to support an injured man during his recovery and convalescence and to pay wage losses due to his vocational handicap during the rest of his industrial life. Whatever was intended the result is, however, that industrial accidents have been greatly reduced since the passage of the compensation laws. Since the cost of accident has

been borne by industry the prevention of them has been good business. Whether or not compensation payment has assisted injured workmen over the rough places in industrial life may be difficult to determine. We know that in all but a few states the

Baking establishments offer some opportunities for the employment of disabled persons. Consequently, when this man was disabled in his employment, he was placed at a task that he could perform in the industry in which he was experienced. Bureau of Rehabilitation, Department of Labor and Industry, Commonwealth of Pennsylvania.

injured workman has been left, handicapped, as he was to seek new work in the way whole people do it. Besides having the range of opportunity for work curtailed by an impaired body, he suffered the additional hardship of sometimes being rejected because of the effort required to place him suitably. We are preparing,

through this joint financing scheme to make an arrangement by which handicapped persons are restored to usefulness, not by a trial and error system, but a system which will estimate a man's assets and proceed to put him in a position to get the maximum use of them.

Persons injured by causes outside of industry are to be rehabilitated by the same social proceeding. Persons afflicted by disease, injured in street accidents, and in public disaster are to be given the same chance to help themselves to more profitable endeavor.

Before vocational rehabilitation is undertaken for any disabled person, every available source, by which physical restoration may be accomplished should be exhausted. Surgeons have accomplished miracles in the transplanting of bone and tendon in the endeavor to make whole the mutilated and broken bodies of victims of disaster and mishap in life. Much more will be accomplished along these lines during the next few years. Similarly the use of mechanical devices and prosthetic appliances will be more general. Genius and mechanical skill are making great impressions in this almost untouched field.

The whole social procedure in rehabilitation takes a person from his handicapped position in life to a new level which gives him as near an equal chance with others as it is possible for him to have. There will be profit, real profit, for individuals, for industry, and for society, where the proper service is given to the handi-

New Jersey holds that industrial rehabilitation is not merely one that looks well and has healed satisfactorily. It implies as complete a restoration of function as is possible under the circumstances, muscular and it may be mental re-education to enable the man to take up his own problems of labor in competition with his fellows.

capped. People are rehabilitated only when they are happily and profitably employed. The scheme is bigger than physical care, bigger than employment, it is bigger than vocational training, it is bigger than advise-ment and guidance. It is a social procedure embracing all of them, and

patch work, if any one of them is neglected.

The United States will have all but few of the states as partners in this undertaking. According to the present available records, thirty-four states are or will very soon, be undertaking the rehabilitation of civilians. The states are required to match the Federal money; they are required to make plans for the conduct of the work by the State Board for Vocational Education, and they are also required to prepare a statement of a working and workable agreement between the State Board and the Compensation Agency. With this done, the machinery is ready to be set in motion.

The program of civilian rehabilitation will fail in its big purpose if, through the accumulation of facts relative to accident and disease, the program of prevention is not forcibly advanced.

State Directors for industrial rehabilitation are being selected from

The operation of a press caused the loss of the greater portion of the right hand of this young lady. She is preparing for a clerical task which is available for her when her training is completed by the Bureau of Rehabilitation, Department of Labor and Industry, Commonwealth of Pennsylvania. Thus are handicaps really welcome.

the field of industry, social service and business. The success of the work will be measured by the vision of the executives and the support and confidence given to the state administration by business and social agencies, by fraternal groups and organizations of workers.

## Milk as a Factor in the Nation's Health\*

### How Health Quotients Would Rise if the Ten Billion Gallons of Milk Used Annually Were Clean!

By J. G. TOWNSEND, SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

*To raise the level of national health is one of the surest ways of raising the level of national happiness.—W. E. H. Lecky.*

**T**O RAISE the level of national health, prevent preventable diseases and thereby insure longer life to the thousands who needlessly die, is the ambition and hope of every sanitarian, local, state, and national.

As milk is perhaps responsible for more sickness and deaths than all other foods combined and is in more nearly universal use, from the cradle to the grave, than any other food, it is a factor all absorbing and ever alive in the health conservation of our body politic. The cardinal points which inaugurate and perpetuate the "milk question" are (1) milk is necessary, (2) milk can be dangerous, (3) milk spoils rapidly, and (4) milk is consumed in the raw state.

I wish in this article to review the proper steps necessary in handling milk from the cow to the ultimate consumer, and, in this chain of sani-

tary control, to emphasize that each link has a significance, which, if not appreciated, weakens the whole procedure in proportion.

With the substitution of cow's milk for mother's milk in infant feeding and its general use as a part of

the modern dietary of all ages in health and disease, the annual consumption of milk in this country, on the average, reaches the enormous figure of ten billion gallons, one-fourth of this being consumed as milk, the remainder as butter and

The first herd in the United States officially declared to be free from tuberculosis.

\*Approved for publication by the Surgeon General.

AUTHOR'S NOTE.—I am indebted to Dr. L. B. Ernst of the Department of Agriculture for the photographs shown in this article.

Type of milk house too frequently found. Bad facilities for storing foster indifferent cleaning and handling.

Cans properly stored in a model milk house. An installation like this makes cleanliness simple and easily enforced.

cheese. Indeed, the cow may be called the "foster mother" of mankind. Naturally, her care and cleanliness is a fit starting-point in the "milk cycle."

**Clean Cows First Essential**

The mechanical washing of the bellies, flanks, and udders of cows, before each milking, to prevent visible dirt from gaining entrance into the milk is a procedure of such obvious necessity as to need no discussion, yet the lack of a proper appreciation of the danger from its neglect or the loss of time it entails to the milker, results in such practice being all too uncommon at the average rural dairy farm.

The Department of Agriculture re-

ports an experiment with open, sterilized milk pails to which samples of fresh milk from dirty cows were added. This milk had an average bacterial count of 55,208 per c.c., while the samples of fresh milk from clean cows, with udders and teats washed, had an average of but 4,947 per c.c.

When we speak of bacterially clean cows, we instinctively think of bovine tuberculosis. Most of the tuberculosis of children is in the bones, joints, and intestinal tract, leading to the belief that milk may be one of the chief causative agents. The theory is also before us that generalized tuberculosis in adults may be the result of the activation of an early infec-

tion in childhood, acquired through the milk from tuberculous cows. This question of bovine and human tuberculosis has been summarized by Hatch, of Indianapolis, as follows:

The only practical way to arrive at any conclusion on this subject is by study of the type of bacillus present in cases of tuberculosis in the human. This study has been made by various observers, who find that approximately one-third of the cases of tuberculosis in children are due to the bovine type of bacillus.

E. C. Schroder in the *Journal of American Veterinary Medicine* of July, 1921, says: "Practically every case of tuberculosis in the human subject, due to bovine bacilli, must be charged to intimate contact, in most cases through the ingestion of contaminated dairy products, between persons and tuberculous cattle."

Rosenau in "Preventive Medicine and Hygiene," 1920, estimates that 7 per cent of all tuberculosis in man is of bovine origin, also that in a total of 551 samples of milk examined in four typical American cities, tubercle bacilli were found in forty-six, a percentage of 8.3, which can be taken as the average for the entire country.

These facts outline a basic health problem of the milk industry and cannot be too widely displayed for the sober contemplation of all milk producers and consumers.

The only way to detect early tuberculosis in cattle is through the medium of the tuberculin test.

Herds may appear perfectly healthy and yet be riddled with tuberculosis. The cows in a diseased herd often do not look materially different from a herd free from tuberculosis.

According to the Department of Agriculture standards, cows should

Part of a 75 per cent tuberculous herd. All animals in this group were classed as reactors, and found to be tuberculous on autopsy. Note the fine appearance of the animals. Seventeen cases out of the fifty-seven condemned were found to be very badly diseased.

be tested for tuberculosis at least once a year, and, if reactors are found, tests should be made twice a year in a herd. All reactors should be removed from the herd and the stables and premises disinfected. All new cows purchased should be tuberculin-tested before associating with the herd.

### Clean Milkers

Of equal importance with clean cows are clean milkers, clean from a standpoint of visible dirt and clean from a standpoint of milk-borne diseases. I have visited a Government-operated dairy farm in which provision was made for clean gowns for milkers and facilities for the thorough cleansing of the hands of each milker. Mechanical cleansing of cows was also religiously carried out, with

tion of typhoid carriers and immunization by inoculation should be, whenever possible, adhered to and insisted upon.

As an example of what might happen from infected milkers, I remember very distinctly, in the summer of 1918, while engaged in public health work at one of the large mobilization camps in the West, of finding a milkman with his throat and tonsils covered with diphtheritic membrane, with a temperature of 103° F. and with all the symptoms of diphtheria, which were later confirmed by a bacteriologist, milking the cows and from time to time coughing over the bucket of milk which was intended for the camp. The only thing that appealed to him, I suppose naturally, when his whole output was condemned and he himself was placed in quaran-

that dairymen would realize that milking into a small-top pail, although perhaps awkward at first, is really just as easy as into the large, open type. It stands to reason that the small-top appliance will of necessity receive less dirt and sediment than the large, open receptacle. The Department of Agriculture has made some very interesting experiments in the relative quantities of sediment in milk drawn into open-top and small-top pails. It appears from these experiments that practically twice as much dirt and filth precipitate into an open-top pail as into that of a closed nature. It has been found by the Department of Agriculture that the average number of bacteria per c.c. in thirty samples drawn into a small-top pail was 29,263, while an equal number of samples drawn into an open-top pail averaged 87,380.

*The Cans.*—From a small-top milk pail, the commodity should be poured through a strainer into a clean can, and then rapidly cooled by packing in ice or submerging in cold water, or immediately pasteurized and cooled. Finally, the milk should be placed in clean, sterilized bottles, securely capped, and properly iced and delivered, or, when the milk is shipped in cans, as is the more common practice at the smaller dairy farms, the cans should be properly iced. The cans should not be allowed to stand on station platforms in the hot sun waiting for the milk train, by which practice they become converted into veritable incubators, and facilitate the propagation of pathogenic bacteria, which know not the meaning of race suicide.

Cans and pails should be of tin and properly washed and sterilized, proper attention being given by the dairymen to the cleansing of the upper rim of the cans and buckets, which very often escapes even vigorous cleansing, and supports a thin, hard crust of dried milk, in which numerous bacteria live and have their being, only to propagate more intensively when fresh milk is added to the utensil.

A type of milk house too frequently found is shown in one of the illustrations presented herewith which represents a group of cans improperly washed, not sterilized, and stored in a work shop. Clean milk production under these conditions is impossible. In contrast, another figure shows properly washed and sterilized cans inverted for drying in a modern and sanitary milk house.

*The Bottles.*—Milk bottles, when

A sanitary milk plant. Washing and steaming cans.

the result that this dairy farm was producing milk with a bacterial count of 4,000 to 6,000 per c.c. without pasteurization. Unfortunately, the custom is all too prevalent at many dairy farms of the milker's rinsing his hands in the first milk drawn, wiping them off on a dirty part of his overalls and then commencing the milking process,—unthinking, and, in all probability, without the slightest conception of what his practice might mean to the community served.

The diseases most commonly recognized as being milk-borne are typhoid fever, scarlet fever, diphtheria, septic sore throat, infantile diarrhoea, tuberculosis, foot and mouth disease, and milk sickness. Frequent examination of milkers for the determina-

tion, was the financial loss involved and not the terrible potential danger which was prevented by this inspection. A series of five hundred milk-caused epidemics tabulated by Trask of the Public Health Service included 317 of typhoid fever, 125 of scarlet fever, 51 of diphtheria, and 7 of epidemic sore throat.

### Clean Utensils

Clean milk will not stay clean if placed in unclean pails, cans, or bottles. A popular recognition of this fact would greatly strengthen this link in the chain of sanitary milk control.

*The Small-Top Pail.*—I wish that the small-top pail were more generally used at the dairy farm and

used on the rural farms, should be given the same scrupulous attention as is given the tinware, being thoroughly washed in soap and water, rinsed in clear water, and, if possible, sterilized with steam before being filled. The proper use of caps for bottles should be emphasized. I have personally seen caps labeled "Pasteurized" inserted on bottles containing unpasteurized milk, merely because there was at that time a scarcity of caps. In this case, the only thought of the dairyman was to meet an emergency, in order that the milk might be delivered, and overlooking the fact that he was guilty of gross misbranding.

The proper sterilization of utensils on rural dairy farms is oftentimes difficult of accomplishment, due to lack of steam or equipment. Bottles, however, can be boiled at any farm and simple forms of sterilizers have been devised for the dairyman by the Bureau of Animal Industry, Department of Agriculture.

### Pasteurization

In 1860-1864, when Pasteur discovered that abnormal fermentation and souring of wine could be prevented by applied heat, he little thought what a boon such a step would become in the milk industry. It was not until 22 years later that heating of milk for infants was advocated by the chemist Soxhlet, and succeeding experiments have developed the modern Pasteurization methods as are known today.

Universal milk Pasteurization would be a signal step in preventive medicine. The process is becoming continually wider in its application, as its value is becoming better known.

Pasteurization is of special moment in creameries, where commodities from numerous outlying dairies are brought in to a central plant and there mixed before being bottled and delivered. I have visited creameries where milk, from a radius of one hundred miles, flowing in from three hundred dairies, met on common ground in the mixing vat, bringing the purest milk produced to the level of the dirtiest, and so the use of applied heat at the distributing point is most important.

It is a most valuable guarantee when individual inspections assume such magnitude as to make such procedures impossible as a means of municipal control. For example; in New York City in 1912, the milk supply averaged 2,500,000 quarts daily. This milk came from 44,000 farms in six states and was the product of

about 350,000 cows. Some of it had to be transported four hundred miles or more. It was estimated that 127,000 people were engaged daily in handling the milk supply of that city.

In brief, there are two methods of Pasteurizing milk:

(A) The "Flash" Process.—The milk flows from the receiving tank to the Pasteurizer, where it is heated at a temperature of 178 degrees F. momentarily and then cooled to 35-45 degrees F.

(B) The "Holding" Process.—This differs from the Flash process, in that the milk is heated only to 145 degrees F., but is kept at that tem-

tion," nor must it be regarded as the all-absorbing factor in pure milk production. It "purifies" milk, but has no influence on the steps which should be taken to render milk pure. It is a sense of false security to depend entirely on Pasteurization, as the "Flash" and "Holding" temperatures and time intervals are so variable at different plants, without constant inspections. Pasteurization should be regarded as an adjunct in the "pure milk business" and a link in the chain of endeavor.

Rapid cooling of the product is necessary to make Pasteurization most effective, and, in any event,

The ideal way to milk in a model sanitary barn.

perature for thirty minutes. It is then cooled as in the Flash process.

Pasteurization in bottles is practiced on a small scale and is the ideal method, as thus reinfection from Pasteurization to the consumer is prevented.

Farm Pasteurization at the average local dairy is most uncommon, due to the lack of its appreciation and the disinclination to incur the expense of such equipment. When it is done, credit is given by the dairyman to its use more as a preservative than as a bacteria destroyer. There are a number of Pasteurizers on the market for the dairy farm and for the home.

While it is duly appreciated that Pasteurization, when properly accomplished, renders inert 99 per cent of the bacteria content, it is not, in itself, a solution of the "milk ques-

milk should be cooled immediately after being received from the cow (to keep down the bacterial count) and conveyed to the consumer as soon as possible. No matter what conditions prevail at the rural farm, cooling, in one way or another, may be easily accomplished, from the method of placing the cans of milk in cold water to the purchase of special apparatus for aeration and cooling. Cooling is another most important safeguard against milk souring. Experiments conducted by the Department of Agriculture have shown that milk at 100 degrees F. will sour in from twelve to thirty-six hours, depending on the initial bacterial content, at 55 degrees F., from 20 to 180 hours, at 40 degrees F., from 180 to 396 hours.

After cooling, the next operation expected of the dairyman is to con-

Conditions connected with milk production, which are far more common than realized.

vey his product to the local market without delay. At this juncture, the sanitarian is confronted with arbitrary hours for the dairyman to make his trips to town in "uncovered wagons" or train schedules, which oftentimes necessitate the milk dealer leaving the milk cans at the station exposed to the hot rays of the sun, facilitating enormous bacterial propagation in a most desirable culture media.

It is possible to keep the milk cool in transit either by the use of insulated cans, which are in reality large thermos bottles, by wrapping ordinary cans in felt jackets, or placing them in sacks filled with ice. The Department of Agriculture accomplished some very interesting experiments, in which four ten-gallon cans of milk, cooled to 44 degrees F. were hauled a distance of fourteen miles to the railroad station. The cans were then shipped by rail in an ordinary baggage car for more than a thousand miles at an average temperature of 80 degrees F. In the unprotected cans, the milk reached a temperature of 60 degrees when they had traveled about ten miles from the farm before reaching the railroad, whereas, milk in the chilled and protected cans did not reach a temperature of 60 degrees F. until after they had traveled nearly four hundred miles on the railroad.

Granting that the dairyman is honestly endeavoring to turn out a supply in conformity with the foregoing necessary procedures, if he has not the requisites of "sanitary" physical surroundings, he has a terrific handicap to overcome.

The water supply in which all

utensils are washed should be of the best, from sources properly protected from subsoil and surface soil pollution, and upgrade or far enough away from the site of excreta disposal to make contamination from the human body impossible.

For a number of years, the United States Public Health Service has been studying the problems of excreta disposal at rural homes and farms and has made extensive surveys in numerous states in its Rural Sanitation Studies. The Septic Tank (L. R.S.), or concrete vault, which requires little more than common sense care, is advocated and should always be evident on dairy farms. The sanitary privy is the "first line trench" against typhoid invasion of milk supplies.

The properly constructed and screened milk house, stable, and milking barn are investments well worth while in the dairy business in helping to give the consumer the opportunity to drink a clean product. Clean stables and barns, with periodical scattering of manure and disposal of garbage, will practically eliminate, or reduce to a minimum, fly breeding and the subsequent danger of filth born disease in milk by a too close association of flies and dairies.

An illustration is presented of a type of combined stable and milking barn, which, being all too common in our country today, is not a far cry from epidemics of disease and death. Would the public tolerate milk brought to them from conditions such as these, if they saw behind the scenes?

The picture presented of a typical modern sanitary milking barn, with

metal stanchions, sanitary gutters, concrete floors, and containing clean cows and milkers is a pleasing contrast. After milking, these cows are driven to a clean, well ventilated stable and the milking barn thoroughly cleaned.

It must be appreciated that all dairymen cannot afford these expensive outlays, but cleanliness is cheap and the sanitarian and general public have a right, at least, to expect that.

The story of safe milk production in itself is not new, but only the practical application of its principles, and, to make these principles more widely known and understood, the story cannot be told too many times.

The United States Public Health Service is ever working on the "milk question" and, through its surveys in rural districts and municipal distributing plants, is striving to assist in safeguarding the supply, to the end that the product furnished may, indeed, be likened to that essence commonly known as "the milk of human kindness," which carries with it health and happiness.

### Institute for Social Welfare Established in Italy

Under the direction of Professor Ettore Levi, member of the Supreme Health Council of Italy, the Italian Institute for Social Welfare, Hygiene and Aid was organized with the endorsement of the League of Red Cross Societies. The aims and functions of the Institute are: to provide a research center for studying causes of disease and means for combating it; to establish an information center on all health and welfare problems for officials, employers and other groups; to act as a clearing house or coordination center for all national and district welfare organizations; to provide a technical and consultation bureau at the disposal of important industrial, commercial and agricultural enterprises; and to provide also a center for testing out new social measures.

### Health Insurance in Spain

According to a dispatch from Madrid in the *New York Times*, a bill providing for compulsory health insurance of all workers in Spain has been approved by the Health Council and will be submitted to the Cortes for adoption. It is expected that the amount to be contributed by the workers will be small though liberal benefits will be awarded.

# An Indigenous Fish Used in Combating Malaria\*

## Once the Causes and Methods of Transmission of Diseases Are Discovered, the Remedy is Simple

BY H. H. HOWARD, M.D., INTERNATIONAL HEALTH BOARD, NEW YORK CITY

THE control of malaria is becoming more and more a matter of interest and concern to sanitarians and those to whom is entrusted the care of the health of the people, as we have come to understand more fully the economic burden to which this disease subjects the people of those sections where it prevails. The people at large are manifesting much more than a casual interest in late years in measures for the control and prevention of this and other diseases, which they are beginning to realize are not unavoidable visitations of Providence, but are preventable ills which are being permitted unnecessarily to exact from them annually a heavy toll through reduced efficiency, lowered vitality, increased susceptibility to tuberculosis and other diseases, and, too often, the untimely death of loved ones.

### A Question of Economics

The economic importance of malaria may be more thoroughly understood when its extent throughout the world is realized. Creighton, in his article on malaria in the *Encyclopedia Britannica*, states that malaria has been estimated to produce one-half of the entire mortality of the human race. As it is the most frequent cause of death in the most densely populated sections of the globe, the estimate may be taken as at least rhetorically correct. Dr. Wickliffe Rose in a recent article states that, of the 1,600,000,000 inhabitants of the world, more than one-half live in countries in which malaria is prevalent. Dr. L. O. Howard, in 1909, estimated that there are 3,000,000 cases of malaria in the United States annually. Since malaria is estimated to take away one-quarter of the productive capacity of the individuals suffering from it, the annual loss for the United States for malaria is said to be not less than one hundred million dollars.

In other countries infection is more severe than in the United States. Dr. Wickliffe Rose states that in India alone malaria causes about 1,130,000 deaths and more than 100,000,000 cases

of illness per year—altogether an estimated economic loss of \$284,000,000, not including the impaired productive power of labor. In Italy about five million acres remain, not uncultivated, but imperfectly cultivated because of malaria. In 1900 Celli estimated the number of cases of malaria per year in Italy at 2,000,000, and the mean annual malaria mortality for a number of years preceding that date at 1,500.

The difficulties which attend the control or prevention of any disease are determined, in a large measure, by the nature of the disease and more especially by the method of its transmission. Malaria, in common with many other diseases, exists and can be transmitted only in the presence of dual hosts—man and the *Anopheles* mosquito. A part of the life cycle of the malarial parasite is spent in the blood of man, and the remainder in the body of the *Anopheles* mosquito. The parasite must be received by the mosquito from the blood of man and undergo a process of growth and development in the body of the mosquito before it reaches the infective stage which will permit the mosquito to transmit it to man. Further changes and developments of the parasite must occur after its introduction into its human host which prepare it for re-entrance into the body of the mosquito. It can thus be seen that in any attempt at the con-

trol or prevention of malaria, there are three logical points of attack: (1) The destruction of the malarial parasite while it is in the blood of man; (2) the prevention of contact between man and the *Anopheles* mosquito; and (3) the destruction of the *Anopheles* mosquito before it can function as a host and in the transmission of the malarial parasite to man.

The destruction of the malarial parasite in the blood of man can be accomplished only by the administration of quinin in proper dosage and for a sufficient length of time.

The prevention of contact between man and the *Anopheles* mosquito may be measurably accomplished by the proper location of homes sufficiently distant from mosquito breeding areas, or by the use of screened habitations and mosquito nets.

### Life Cycle of the Mosquito

It is the purpose of this article to discuss the third and last point of attack, i.e., the destruction of the *Anopheles* mosquito before it can function as a host and in the transmission of the malarial parasite to man, and to do so intelligently we must first know something of the life cycle of the *Anopheles* mosquito.

There are three active stages in the life cycle of the mosquito, the larval and pupal stages, which comprise the aquatic life of the mosquito, and the

No. 1. View of portion of district. Showing gully formation due to erosion from rainfall and storm water

No. 2. View of portion of district. Photograph taken after one of the infrequent snow storms which are experienced in central Mississippi

imago or winged adult mosquito. The female mosquito deposits her eggs upon the surface of the water, the eggs hatch into larvae—"wrigglers" or "wiggle-tails"—in from twenty-four hours to a few days, the time varying with temperature and other environmental factors. The larval stage requires from one to three weeks, being shortest in tropical climates. The pupal stage is commonly short, lasting only for a day or two when the imago, or winged adult mosquito, emerges. The normal life time of the female mosquito is said to be about three months, though under certain conditions their life time may be much prolonged.

The male mosquito, like the drone bee, is of short life and serves only to fertilize the female. The female mosquito only is concerned in the transmission of disease.

In mosquito control the minimum time required for the development of the mature mosquito from the egg, ten to twelve days, is taken as the basis for the formulation of control measures.

It is during the aquatic stage of its existence, i.e., prior to its winged life, that the mosquito is most vulnerable to attack, and it is likely for this reason that for years the sanitarian has directed his attention in the main to its control or destruction during this period by the several methods of drainage, oiling, larvicides, etc. These methods, while often effective, seem practically prohibitive in cost if we would attempt to apply them to the immense area of the world's surface, and the great population which must be handled if malaria is ever to be controlled.

Not the least valuable contribution made through the science of entomol-

ogy to the world's knowledge has been the discoveries which have made possible the control of certain devastating insects, which have from time to time threatened some great industry, by introducing and marshaling against them some other insect or agency which would, as a natural enemy, attack and destroy them, or at least greatly limit their activities and powers for harm. Notable instances of this sort are as follows:

The introduction of the ladybird or ladybug, a beetle of the family of Coccinillidae, for the control of scale insects and plant lice; the control of the brown tail and gypsy moths in New England by the introduction from Europe of the parasites of these moths; the ordinary cabbage worm (*Pontia rapae*) is combated by an Ichneumon fly (the *Apanteles glomeratus*). This fly was imported in

No. 3. Stock Pond. More than eighty stock ponds were found in the district, many of which were breeding *Anopheles* mosquitos profusely. The ponds were essential for the convenience of the people and could not be filled or drained. Experiments with oiling showed that this measure was ineffective to prevent mosquito breeding in the ponds, and oiling also rendered the water unfit for the stock. Had it not been for the use of the top minnow to control mosquito breeding in the ponds, mosquito control would have been rendered impossible.

1883 from England and it has been applied with success.

### Great Economy of Effort

This pitting of Nature against herself, where effective, has in every instance had the advantage of great economy in cost and effort as compared with any purely artificial means of control.

Many years have now elapsed since we first knew of the important rôle played by the mosquito in the transmission of disease, during which time many artificial methods of control of mosquito production were developed and practised, all of which were expensive in application and, with the exception of permanent drainage schemes, were neither entirely satisfactory nor certain in their results. It was remarkable that during this time no attempt was made to find a natural enemy with which to combat the mosquito, or to develop or test in a systematic manner those agents in nature which have been casually mentioned or recommended by various writers for this purpose from time to time.

Professor A. C. Chandler, of the Oregon Agricultural College, writes as follows:

Up to this time (1919) practically no use has been made of the natural enemies of the mosquitoes. Application of kerosene to the water to kill mosquito larvae at the same time make it an unbearable place for the natural enemies of mosquitoes, and so things may be worse off than before unless the applications are continually repeated.

The following statement bearing upon the same matter appears in Volume No. 1, "The Mosquitoes of

North and Central America and the West Indies," by Howard, Dyer, and Knab:

Almost no use has been made artificially of the natural enemies of mosquitoes except fish. . . . For a long time fish have been used practically on a small scale. . . . In the Southern States for many years intelligent persons here and there have introduced fish into water tanks for this purpose.

Quite a number of successful experiments in the control of malaria in towns and other centers of population by anti-mosquito measures have been made and reported. The measures employed in these experiments were the usual ones of drainage, filling, edging of pond, stream and ditch banks, removing heavy vegetation and debris, the training of ditch and stream beds, and oiling. While a scheme comprising these measures of mosquito control is applicable to urban communities and centers of population at a non-prohibitive cost, such is not the case when we seek to apply them to rural sections where conditions are very different in several aspects, i.e.:

(1) In rural sections we have a sparse population, often unevenly distributed, where the area controlled per individual is large, in consequence of which the per capita cost of mosquito control, if we confine ourselves to the above mentioned measures, is likely to be very high.

(2) Rural communities have no drainage system or means of disposal of storm water such as is commonly found in towns.

(3) There is no system of sanitary laws and regulations in rural communities, nor is the official machinery in existence for the enforcement of such laws and regulations.

(4) No easily applicable system of local taxation is provided by law for

rural and unincorporated communities, by which funds can be raised to meet the cost of control work.

Realizing the need for more definite information regarding the incidence of malaria in rural communities, and the possibilities of developing cheaper methods of control, the International Health Board, in cooperation with the Mississippi State Board of Health, early in 1918 selected a rural district in Hinds County, Mississippi, in the hill section of the state, where observations and experimental measures of control might be conducted for a period of three years. The author of this article was placed in charge of the experiment. The district selected was in the northern part of Hinds County and comprised territory to the extent of approximately thirty-six square miles. The district seemed to represent average conditions in the hill sections of the great malaria belt of the Southern States as regards distribution of population, agricultural products, and methods of cultivation, climate, rainfall, soil, and drainage, with conditions neither more or less favorable than the average for mosquito production. There were 172 homes in the district housing 830 people, most of whom were engaged in agricultural pursuits. The season of 1918 was given over entirely to observations and the study of conditions in the district, no attempt being made to control mosquito production or in any way to influence the prevalence of malaria.

#### The Situation Surveyed

The district was mapped as a whole and also individual maps were made of each home and the territory surrounding it for one-quarter of a mile in all directions. On this individual map were located all water deposits which might or were already pro-

No. 5. Fish pond, showing spillway with fish guard of 16-gauge wire netting. This shows a fish pond of large size, having a shore line of 720 yards. This pond was owned by a fishing club, and was stocked with black bass, bream, sun perch and the top minnow (*Gambusia Affinis*). Black bass were added each season to the number of one thousand or more by the fishing club to replace those caught from the pond. It is interesting to note that in spite of the presence of a great number of predatory fish in the pond, the top minnows thrived and increased to such numbers that during the season 1920 we were able to remove four thousand minnows from the pond for stocking purposes, without disturbing the complete control of mosquito breeding, which was maintained in the pond by the minnows throughout the three years in which it was kept under observation.

ducing mosquitoes, and these water deposits were kept under careful observation throughout the season, a study being made of the conditions in each which seemed to favor, limit or prevent mosquito production. A census of the entire population was taken, clinical histories of all illness of the people during 1918 and the previous year were secured, blood smears were obtained from a representative number and class of people and examined to establish a blood index, mosquitoes were caught, and larvae collected and hatched for identification. The results of the observations in 1918 were briefly as follows:

The rate per cent of malaria in 1918 among the people living in the district, based upon clinical histories, was 29.14 among the whites and 13.67 among the blacks, or a rate of 17.83 for the entire population. The examination of blood smears gave a parasite index of 6.28 per cent among the whites and 5.89 per cent among the blacks. Out of the thirty-eight people

No. 4. Stock pond, cleaned and edged, ready for stocking with fish

showing some form of the malarial parasite in their blood, thirty were without clinical symptoms. The combination of the positive blood findings and clinical cases of malaria gave a total of 178 cases of malarial infection in a population of 830 people, or a rate per cent of 21.44.

It may be of interest to know that more than one out of every three of the whites had malaria, and approximately one out of every six of the blacks. Blood smears were collected and examined again in the winter of 1918-1919 with the result that a positive rate of 2.09 per cent was found for all races.

Two hundred twenty-eight water deposits were located in the district consisting of creeks, branches, ditches, lakes, ponds, potholes, pools, springs, seepage areas, borrow pits, cattle dipping vats, wells, and cisterns.

Of the 228 water deposits which were kept under observation, 167 were producing malarial mosquitoes (*Anopheles*) for a part or all of the season of 1918. Many *Culex*, or common mosquitoes, were hatched in small water deposits near the homes of the people and in artificial containers, such as tubs, rain-barrels, and cans, in which water was allowed to stand. It was mainly from these sources that the mosquitoes came which annoyed the people and caused complaint of the mosquito nuisance. The *Anopheles Punctipennis*, *Quadrifasciatus*, and *Crucians* were identified as common in

No. 6. A pond bank having a heavy growth of water grass which must be removed before the top minnow can reach and devour the mosquito larvae.

No. 7. Pot holes are often very prolific breeders of malarial mosquitos, and where at all practicable should be filled or drained and thus permanently eliminated. Where it is not feasible to fill or drain them, it was shown by our experiments that mosquito breeding may be easily controlled in them by introducing the top minnow.

the district. In the study of the water deposits of the district, and the conditions which favored, limited or prevented mosquito production, it was early noted that under natural conditions, without our aid or intervention, the indigenous, top feeding minnows which were found in many of the larger water deposits of the district, were maintaining a fair degree of mosquito control in these deposits by feeding upon and destroying the eggs and larvae of the mosquitoes. There were three varieties of the top feeding minnows present in the district (*Gambusia Affinis*, *Fundulus Natalus*, and *Fundulus Nottii*), but only the *Gambusia Affinis* was present in any great numbers, and it was this fish which was functioning actively as a natural agent of mosquito control.

The *Gambusia* is the common top water fish found throughout the hill sections of Mississippi and many other Southern States. Its distribution in the United States, as stated by the United States Bureau of Fisheries, is as follows:

The *Gambusia Affinis* is found in fresh and brackish water from New Jersey to Florida, and in the Mississippi Valley from Illinois to Louisiana, and thence to the regions of Texas and Mexico. It is excessively abundant in the southern part of the area outlined above.

At the beginning of the active malaria season of 1919, with the information obtained in 1918, plans were made for controlling mosquito production. An area consisting of a part of the observation area of 1918, and containing approximately twenty-two square miles, was selected in which the attempt to control mosquito production was to be made. The area contained 142 homes, housing 593 people. The remaining fourteen

square miles of the 1918 observation district, containing thirty homes and approximately 237 people, was retained under observation as a control area no measures for mosquito control being instituted. Anti-mosquito measures in the controlled area consisted of drainage and filling, training of stream and ditch channels, clearing away brush, vegetation, and debris, and oiling in emergencies where other measures of control were not applicable. At the same time a program was arranged to increase the number of top minnows and to test them as agents of mosquito control in all classes of water deposits. The heavy precipitation occurring in the period from January to May, 1919, the continuous flooding of the lowlands, and the flooded conditions prevailing in practically all water deposits in the districts greatly delayed field work, and it was not until July 1 that the entire area was under control. Mosquito control was secured by the application of the following measures:

1. Drainage and filling: 25 water deposits were drained, or partly drained, and 4 filled.
2. Removal of debris and obstructions from and the straightening and training of stream channels, ditches, etc.: 9,552 yards of streams and ditches were so treated.
3. Removal of grass, weeds, brush and aquatic vegetation from, and the edging of the banks of ponds, pools, pot holes, etc.: Thirty-six ponds and numerous pools and pot holes, having a total shore line of approximately four thousand yards, were cleaned and edged and kept so throughout the season.

No. 8. Pot hole filled with brush and earth. The brush was used to prevent the earth being washed out during heavy rainfalls

Oiling was used as an emergency measure whenever other measures of control were not immediately appli-

cable. A total of 178 $\frac{3}{4}$  gallons of oil were used during the season of 1919.

(To be continued)

## Shoe Fitting Becomes a Science

BY SOLOMON STROUSE, M.D., CHICAGO, ILLINOIS

A FEW DAYS ago a business man told the following story: "I had at least twenty pairs of shoes at home, and could not wear a single pair longer than a week. No one seemed able to give me the proper shoe. Whether they were custom made or bought from stock, I could get no real foot comfort. And not having real foot comfort made me feel out of sorts all over. Finally, a doctor friend advised me to go to a shoe store where they are more interested in properly fitting shoes than in shoe sales, and where all the salesmen have made a special study of feet and shoes. Although naturally skeptical, I did finally try them out, did finally get shoes which fit my feet and give me solid comfort."

This is not an exaggerated statement. Most individuals would be unable to maintain a stock of twenty pairs of shoes, but there are only too many people whose complete stock of one pair represents a stock of misfits. Foot comfort is a rare thing to find. Usually people do not know a properly fitting shoe when they feel it on the foot. As a result many shoe salesmen find it possible to sell shoes which are uncomfortable and which ultimately do harm.

We are prompted to open a discussion of feet and shoes because of the universality of the complaint. Poorly

fitted shoes and their relation to the health of a nation have never received the attention the subject deserves—except in war, when it becomes imperative that every effort be made to keep the feet of the soldiers in condition for service. During peace times shoes are bought like ties, without any relation to the individual anatomical peculiarities of the "patient." We use the word patient advisedly, for no prospective buyer of a pair of shoes should be regarded merely as a customer. No two pairs of feet are alike. One man with a six and one-half length has a heel A, an instep B, and a ball C; the next has six and one-half B all around. One man's arch needs a given kind of support, an aid which the next man does not require.

The buyer, of course, knows little about his own feet. The seller *must*, and it is up to the salesman to provide proper fits. Speaking in a general sense, the buyer gets not what he needs, but what there is in stock. This used to hold good even in first class shoe shops, although we believe there is a notably increasing attention to feet and the fundamental principles of shoe fitting on the part of the better shoe merchants.

But why all this fuss? Suppose a shoe does pinch, it is on my foot. There is a logical answer to this ques-

tion, too. The extent of the damage of poorly fitting shoes is not limited to the feet of the wearer. An undiagnosed flat foot or a weak arch improperly corrected may render an individual tired and uncomfortable, but it does much more than that. He may have pains in his back (he calls 'em kidney pains); he probably is too tired to take the amount of physical exercise his health requires; he becomes neurasthenic; he resorts to medical care; his whole family suffers. We know of one man who suffered for years before his physician found the foot trouble which alone was responsible for his varied assortment of ailments. Another victim came to our office a few years ago scared beyond description because he had "fainted" in a theater aisle while escorting a charming lady. He had not fainted; his feet had merely given way. Proper attention to his shoes made him so comfortable and happy that he married the lady.

Instances could be cited to show the relation between fatigue phenomena and the feet, between "neurasthenia" and weak arches. It is only necessary to call attention to them. The several phases of this subject will be treated from many angles in a series of articles to be presented by THE NATION'S HEALTH in the next few months. Our main proposition is quite simple. Many individuals suffer from foot ailments which are either caused or aggravated by the improper fitting of shoes. The arousing of public opinion against the evils of the old time tight corset certainly carried as a result an improvement in the general health of the women of the Nation. We wish to arouse public opinion to a realization of the need of better fitting shoes, to make them demand the application of a little science to the art of selling shoes. We hope to prove that better shoes mean better health. If the public comes to demand more fit and less style, the manufacturers must supply the demand. We believe they are only too willing.

Yonkers, New York, wastes 133,000,000 gallons of water yearly, a recent survey of the municipal water main system shows. The loss in money is estimated at over \$13,000. Recommendations, which if followed, will avoid future waste, have been made to the municipal government. Better installations will be supplemented by service bulletins to sell the idea of water economy to the citizenry.

# Recent Child Welfare Expositions in France

## We Can Visualize a Nation's Future by Its Care of the Child

BY THEODORE C. MERRILL, M.D., MEDICAL DIRECTOR, DEPARTMENT DU NORD, PARIS, FRANCE

IN THE spring of 1918, refugees, tuberculosis, and child welfare problems became acute throughout the warring nations. War-time activities of the ameliorating organizations were at their height. So far as the American Red Cross was concerned, its funds at this time permitted work on a scale which, since the armistice, has been gradually shrinking, notwithstanding several periods of augmentation in response to critical situations needing relief.

Among special efforts of this period, the American Red Cross organized child welfare exhibits at several cities in the south of France. These were complete, successful, and applied a vigorous stimulus for home creation of child welfare agencies. These new (French) agencies took up their work, the acute war situation passed and the expositions, ceasing to operate, were regarded as closed incidents in philanthropic history.

### A Population Problem

Even before the war, depopulation in France had become alarming. After the war, it forced itself insistently upon the attention of the entire French public. France was facing the possibility of extinction. As if in response to a natural urge, practical manifestations of a strong national sentiment for repopulation began to appear. These manifestations were linked with past experience.

The people of the south of France remembered the American child welfare expositions. Some of them were closely associated with reviving industrial centers in the devastated region. Moreover, it was from the wasted cities in the north of France that many hapless refugees, expelled from the front, had drifted to shelter in the South; and these refugees, gradually returning to their homes, carried with them memories of the American ameliorating enterprises with which they had been in contact during the days of their exile.

The French reaction, beginning but now to be effective, takes the form of new life to open-air schools; honors large families; promotes play-

grounds; favors milk stations, prenatal clinics, maternity hospitals, better obstetric care, physical education, breast-feeding, provision for working mothers, visiting and school nurses, preventoriums, school canteens, school medical inspection, model dairies, personal and public hygiene—in short, stresses every interest of the prospective and actual mother, of the infant, child, and adolescent.

held from June 15 to July 25, was another; the cities of Cambrai, Douai and Soissons, again call the exposition to the north.

### The New Baby Show

The present set-up makes freer use of really artistic material than do expositions ordinarily seen in America. The general tone has also to consider French, rather than American, temperament and point of view. Ideas and material used at the former expositions have been utilized. French organizations have cooperated. Assistance has been rendered by the Ecole de Puériculture at Paris, the Florence Nightingale School of Nursing at Bordeaux, League of Red Cross Societies, Rockefeller Tuberculosis Commission, American Committee for the Devastated Regions, other agencies and many individuals.

The material is active or living, and passive or static. Living features provide the stronger impression and mark the difference between European and American conceptions. Living departments of the present expositions consist of the weighing and measuring of children; preparation and care of milk, nursing bottles and nipples; specimen diets, demonstration of correct foods and principles of nutrition; clothing for infants, children and prospective mothers; dental and oral hygiene; weighing and bathing of babies; typical kindergartens and playgrounds; movies and lantern slides; a Guignol or marionette show, dear to the French child and combining instruction with amusement; music; health talks by local physicians; baby contests, based on physical excellence; post-card essay competitions. Parenthetically, it may be stated that a screened couch and simple restoratives are indispensable for meeting little emergencies that are sure to develop in the course of any program contemplating the massing of crowds.

Static exhibits consist of thirty posters covering maternal, infant, and child hygiene and painted by Poulbot, the well known child-life artist of France; twenty-six posters by Miss Upjohn, which were obtained from the American Red Cross Muse-

This French poster will make friends in America.

In this impulse, American cooperation is not forgotten. The child welfare expositions of 1918 now prove to be the genesis of similar assistance, thus recalled to life and started over again, at French request, in the industrial town of Roubaix, of the Department of the Nord. The American Red Cross was the organization to which the French naturally looked for a renewal of former expositions.

The revival seems chiefly to interest the devastated region. Roubaix, Tourcoing and Lille were the first of the recent objectives, the periods being April 24-30, for Roubaix; May 4-10, for Tourcoing; and May 15-30, for Lille. The exposition at Paris,

The interior of the exposition hall, the Palais Rameau, at Lille.

um at Washington; a glass-paneled house, or room, about twenty feet square, for the weighing and bathing of infants and provided with beautiful panels painted by Madame Dick Dumas; miscellaneous posters and charts showing birth and death rates, infant mortality rates and causes, standards for height, weight, and infant feeding; printed matter for use at the booths; an artistic façade or entrance piece a simple cloth velum; literature for distribution and posters for billing the town.

#### Depends on the Budget

Everything starts with the budget. For the expositions shown at Roubaix, Tourcoing, and Lille, the sum of ten thousand dollars were provided. It was intended to cover the preparation of material, transportation, and hotel bills, but did not cover the salaries of all the personnel. The latter numbered from fifteen to eighteen and an additional allowance of at least two thousand dollars should be counted in. Fifteen thousand dollars would about cover the expense from the opening labors in February to the close at Lille on May 30. It must be remembered that the exposition sites, lighting, water, and a good deal of labor were provided by the municipalities. Beautifully artistic material was painted at special concessions on account of the end in view; organizations and individuals contributed valuable services free of charge.

The practical demonstrations were

exceedingly popular. Many applicants for babies baths had to be turned away and the audience at bathing hours was always large and keenly interested. The crowd about the dentist's stand threatened to swamp the workers and often required the special attention of a gendarme. Milk, diet, and clothing booths started free discussion; differences between French and American ideas as to coffee, wine, constricting

garments, and the use of pacifiers occasionally created acute situations.

Weighing and measuring were done according to American figures, reduced to the metric system. The sitting height was recorded, after the pelidisi formula developed, with other inventions, by Dr. Pirquet, of Vienna. These novel principles are expounded in his "System of Nutrition" and have proved very useful to the American Relief Administration in their extensive child feeding operations in Europe.

For the kindergarten (*jardin d'enfant*), cinema (movies), Guignol and playgrounds, special reservation was made for morning attendance by the school children, who came in orderly groups accompanied by their teachers. Baby contests were arranged in three classes—0 to 6 months, 6 to 12 months, and 12 to 18 months. At Lille an extra class for twins was added, the entries being twenty-six. Money for the prizes was offered by the American Red Cross, the French citizens adding generous contributions of their own. Prizes consisted of twenty, fifteen and ten francs each, and a large number of diplomas were issued. Registration for the contests was ample and enthusiastic and service by the French physicians very thorough. The necessary examinations were painstakingly made, regardless of long hours and fatigue. Health talks were closely listened to; music proved almost a *sine qua non*, itself an injection of vitality.

Statistics, admittedly the dryest

The children eagerly came to attend the kindergarten.

part of an exhibit, were of special interest here because of the painful evidence of France's decline in the birth rate before and during the war and the ray of encouragement shown in an increase as revealed by the figures for 1919 and the first half of 1920. War and influenza effects were carefully noted. Many persons returned again and again to the exposition to study the charts and posters. The Poulbot paintings, full of French charm, were most attractive. The legends for these were prepared by a committee of well known physicians and social workers, carefully translated into French and they constitute a library in themselves. The Dumas and Upjohn decorations were also much admired.

The vellum was made of simple white cloth, on which were painted animals and stars. A twelve-inch border was obtained by ordinary laundry bluing. The vellum was very useful, a great addition to the rather bare and lofty hall occupied at Rouhaix.

Flooring was accepted as it occurred. At Roubaix, it consisted of bricks laid rather irregularly in earth. At Tourcoing, it was a pavement of smooth stone. At Lille it was of sand and earth, frequent watering being necessary. At Paris, the American portion of the exposition was under canvas and floored by grass. Dry sand or earth cause too much earth. Sawdust should never be used, as it is easily displaceable and adds a serious fire menace. Tanbark was not available.

The animals on this marionette show tent were put there with stencils.

Entering upon its work at the solicitation of the French, the exposition naturally found a cordial welcome and full cooperation at their hands. At the outset, the position of the exposition was made clear to municipal and medical authorities and thus placed under official sanction and guaranty. Official indorsement of this kind is indispensable, not only in foreign countries, but in America as well. Public authorities and the medical fraternity are entitled to

consideration and respect equally at Stringtown on the pike as at Chalons on the Marne.

Next after official cooperation came that of the French organizations, or Oeuvres, as they are appropriately called. Among these were the French Red Cross, tuberculosis dispensaries, societies for honoring large families, milk stations (Gouttes de Lait), consultations de nourrissons, soup kitchens, gymnastic clubs, and other welfare associations. At Roubaix and Tourcoing, these organizations occupied about half the space within the main hall.

At these two places, the exposition was the principal attraction and ran itself. At Lille and Paris, it was one feature among many, the whole being under French direction and conducted according to French ideas.

#### Practical Conclusions

(1) Support by public and medical authorities, cooperation with local organizations, and care to keep free of religious and political differences are indispensable conditions.

(2) A wealth of material is desirable. Health topics are thus presented from many angles and many mentalities and temperaments will be appealed to.

(3) Objective demonstrations are especially important. They develop the most interest, make the strongest impression and leave lasting memories if they are really excellent.

(4) Static material should be carefully prepared. Clearly drawn charts

The interior of the glass bathroom, all set for action.

and diagrams and artistic decoration applied to panels, stands, and literature are second only to the living portions of the exhibit. Opinions may differ as to arrangement. However, it is safer to group the material so that the hygienic teaching may be concentrated rather than to arrange posters and legends indiscriminately. Confused and purposeless placing should not be permitted. Sometimes a little elasticity for the sake of artistic unity is permissible, but such elasticity should not be abused.

(5) Stands or booths will generally correspond to those whose work is here described. See "The New Baby Show," active material. A tuberculosis stand should not be omitted; at least there should be special tuberculosis posters and literature. Booklets and other tuberculosis teaching were abundantly provided at this exposition, but there was no demonstration-booth.

(6) If the budget permits, it may sometimes be feasible to have eye, ear, nose, and throat examination of children, solely for giving advice. Local physicians are likely to be very sensitive if exposition work encroaches on treatment. Anything that may lead to misunderstanding should be avoided. For instance, at Roubaix and Tourcoing the stand for weighing and measuring was labelled "Practical Consultations." The dental stand bore the legend "Dentist." At Lille the physicians requested that these wordings be changed respectively to "Weighing and Measuring" and "Hygiene of the Mouth." Again, diagnosis should generally be avoided. It is usually impracticable to make examinations thoroughly enough to be sure of all the diagnostic condi-

The exterior of the "bath room," with panel by Madame Dumas.

tions, and imperfect examinations or mistakes lead to criticism by local doctors. A diagnosis differing from that made by the attending physician invites trouble. Should the condition of a subject indicate further diagnosis or treatment, he should be referred to his family physician or to a dispensary, clinic, milk station, etc.

(7) Projection should receive special attention. The cinema, or movie, has been so perfected that poor illumination and faulty film showing will detract much from the effect desired.

(8) For foreign effort, it is desirable that at least some of the American personnel should be able to use, in a creditable manner, the language of the country where the exposition is held. Without this resource, one must depend on interpreters and other foreign people for meeting officials, paying bills, talking to the public, presenting speakers to the audiences and representing America in a social and diplomatic capacity. Much of the force of an American exhibit depends on the fact that it is American and that it represents a powerful and benevolent American organization. For this reason, it is regrettable when capable representation must pass to other than American hands and when American members of the exposition must remain dumb and helpless in the presence of foreign officials, prelates, people of position, and the public at large. I

am strongly against permitting the director of an American exposition in a foreign country to be other than an American. It is poor policy to allow any but a most exceptional foreigner to undertake to represent American ideas and ideals. The greatest care should be taken in securing foreign representatives to see that their character and position are really what these qualities are pretended to be. Americans do not understand the highly specialized brands of impostors that are floating about Europe, and a few simple data, such as place and date of birth, address, military service with number of regiment and satisfactory references, should invariably be secured and placed on file. Organizations may be saved much humiliation and sometimes money by observing such precautions.

(9) The Paris exposition has proved very suggestive. In the first place, it must be judged somewhat differently from the expositions held in smaller places. Two great differences are, first, that the Paris public sees so many expositions that attendance may not be proportionally large when compared with the visitors attending in less important towns; second, although the attendance may seem small, it may include persons from many parts of the country as well as visitors from foreign lands, so that the exposition's influence may spread widely. Apart from these two considerations, however, four in-

'Most ready to open?

fluences were against full success at the Paris show:

(a) *Season*.—The exhibit began just as the summer heat was making itself, and continued through a long and very uncomfortable period. Many of the Paris citizens were absent from the city, which fact lessened attendance considerably.

(b) *Location*.—The exposition was placed in the Jardin d'Acclimatation, in the Bois de Boulogne, and was eccentric not only to the city as a whole, but especially so with reference to the people who should be most benefited. People of the poorer and more populous quarters of Paris could visit the exposition and take their children only by paying for transportation and, in any event, incurring expense and fatigue.

(c) The public was admitted free. Exaction of an entrance fee makes

against conveying the ideas of a welfare exposition to the people who need such service most.

(d) An unfortunate commercial element was present. The most accessible and conspicuous sites were assigned to patent foods, soap, and talcum, furniture, clothing, household articles, etc. The welfare organizations were thus deprived of the best places. Lessened publicity was another result, since publicity agencies are not enthusiastic about supplying free advertising for commercial firms.

The lessons thus suggested by the Paris exposition are of great value. Present comment is designed to be constructive. This article will probably be read by French physicians and socially interested people, and the French open-mindedness will be perfectly willing to consider the

American viewpoint and translate it into Gallic terms. May Americans reciprocate this tolerance! I cannot close without reference to the organizing ability of the French physicians, and others, who guided the exposition and contributed great labor for its success. Notably is this true of the baby contests, which were planned and managed according to French methods. Technical ability, expedition, thoroughness, and disregard of self characterized this work. It is a labor of duty, as well as of affection, to record this tribute. It is no less a privilege and honor to make, before the American public of physicians, teachers, and social benefactors an acknowledgement of the kindnesses granted, freely and delightfully, by the officials, organizations and individuals who were our hosts.

## Preventive Measures Effective in Cardiac Disease

It Is Not Enough to Know the Remedy.  
Correctives Must Be Readily Available.

By LOUIS I. HARRIS, M.D., DR.P.H., DIRECTOR, BUREAU OF PREVENTABLE DISEASES, DEPARTMENT OF HEALTH, NEW YORK CITY

IT HAS become fashionable for those interested in public health to talk of education as if it were a cure-all, notwithstanding the fact that experience has shown that educational methods are slow in producing results and that the general apathy and indifference to public health instruction even on the part of the relatively intelligent, is still colossal. Moreover, there are many who know full well the dangers inherent in living in overcrowded quarters which invite infection, and who know also about the hazards to health from excessive physical strain or exposure to industrial poisons and various toxic agents, as well as the dangers in certain other social and physical factors which are conducive to, or immediately provocative of organic cardiac defects. The young housewife might possibly know that the number of fatalities annually among housewives from organic heart disease is very considerable and yet the needs of the family and the economic handicap under which she lives may compel her to do comparatively hard labor in the home. The farmer, the blacksmith, the steel mill worker, the laborer, and many other occupational groups might conceivably, under instruction, become thoroughly conver-

*The incompetent heart must not be allowed to work beyond its power of recuperation and the limits of safety need to be determined for each affected individual.*

*The intelligent and economically independent may be able to avoid the perils of overwork, anxiety, or other strain, but public protection must be afforded the socially unfortunate in order to improve surroundings and regulate habits which operate as unwholesome factors. In both cases systematic supervision by fully organized clinical units is the minimum essential.*

sant with the dangers of cardiac disease and yet find themselves only partially able to guard themselves against the dangers which may lurk in their industrial or social environment.

Something more than mere knowledge is needed. Nevertheless, education of the great masses of people must of course be conducted with energy and consistency. It must be education of a character that shows

in terms of dollars and cents that it pays to safeguard the human machine. Even at the risk of being accused of paternalism, public health officers should, by reason of their experience, preach not only good health *per se*, but should become the staunchest and most fearless teachers of the doctrine that human life at any and every age has value not only in terms of dollars and cents, but has a sanctity and individual claim for regard which is greater than any money value. Education that is not merely academic and physiological, but which is inspired by a spiritual conception and a reverence for human life, should make every public health officer the unrelenting critic and opponent of prevailing conditions in the social and economic system which contribute toward a preventable and merciless waste of human life. Our educational campaign has been too much of the Simon-pure variety, based exclusively on considerations of physiology and dollars and cents. One may make bold to say that education animated by a spiritual ideal is not the dream of a visionary, but should become the pattern adopted by every public health officer. With proper housing conditions that prevent too intimate contact and exposure to in-

fection, with means for an adequate dietary, with sufficient means also to enable one to punctuate work with a vacation at necessary intervals, a great deal could be done to prevent organic cardiac defects or to hold in check the progress of cardiac disease already established. However, these are objectives which will have to be attained by other means and must be expected to develop in the slow evolution of things.

The point that is here expressly made is that one should not rest too confidently on the idea that education by itself will remedy conditions. It may measurably influence personal conduct, personal habits, and will be of some aid in improving general conditions. It is also desired to emphasize that education in a dispassionate, academic fashion on matters of public health is not sufficient; that public health must be treated as one of the humanities and as such it should be inspired by a broad social vision, and those employing educational methods should not hesitate to give testimony as to the relation that exists between economic and social conditions and the prevention of cardiac and other preventable diseases.

The relation that has long since been established between syphilis and, in rarer instances, between gonorrhoea and the subsequent development of organic heart disease, should be brought home to the young especially, as well as those who are about to marry. In our educational campaign, special emphasis should be given not only to the prevention of exposure to infection but also to the necessity of prompt and long-continued medical observation and treatment for those suffering from syphilis.

In adult life, as in childhood, focal infections play a most important rôle in the etiology of cardiac diseases. This should be made known in the educational propaganda in simple terms, through factory talks, literature, etc.

The avoidance of excesses in diet and in the sexual life, and the avoidance of habits which are conducive to undernourishment and fatigue, should also be made part of the message of warning to be carried through the educational campaign in newspapers, lectures, and literature.

Publication notes in newspapers, and, if necessary, paid advertisements in newspapers, magazines, and the other familiar forms of educational publicity, should be utilized at frequent intervals to force home upon the average apathetic and indifferent person the dramatic features which

have publicity value and which portray the causes, incidence, mortality rate, and the methods of prevention of cardiac diseases.

### Periodic Medical Examination

While much headway has been made in persuading people to submit to periodic medical examination, a great deal more remains to be done even in those communities that have made progress along these lines. Those having ample means should be made to feel it a pressing duty to be examined by their private physicians at regular intervals, and that it is a menace to life to omit such procedure. Public health officials should so spread their educational propaganda that they will teach people to look upon their family practitioner not merely as one who gives aid in times of grave emergency or when sickness has already manifested itself, but who, by periodic examination of his patients, will be enabled to detect the beginnings of cardiac and other preventable disease in time to influence the patient's future, so far as possible, by proper counsel and treatment. Periodic examinations of persons in all age groups who cannot afford to pay for private "health" examinations should be the most conspicuous preventive function of health departments. These should be conducted at frequent and regular intervals, in the various dispensaries and clinics of the general hospitals and of the health departments which at the present time ignore the necessity of examining persons who have no specific complaints.

Periodic health examination clinics should be amply provided, where other means are lacking, by the establishment of additional Health Department Clinics in various centers of population or by the traveling clinic. The Health Department of New York City has not yet attempted to organize a traveling clinic for the detection of cardiac diseases, tuberculosis, and other preventable diseases. Efforts should be made without delay to bring home to the people of the city as a whole and to the budget-making officers of the city, that it is in the interest of industrial, community, and individual economy, and in the interest of humanity itself, to establish the necessary number of stationary and traveling clinics, and to provide adequate personnel for the purpose. It should be brought home to all citizens, however distantly related they may think themselves to this problem, that it is good business and that it pays to provide ample means for the

periodic examination of individuals. In connection with such periodic examinations for children of pre-school age, as well as for school children, for adolescents, and for adults, the various official and non-official dispensaries and clinics should have it impressed upon them, no matter what their special field of study or interest may be, to note carefully in their routine examination any other preventable disease which they may be able to detect, and to refer persons for the care and correction of physical defects to private physicians or to proper institutions, and to have nurses to follow up and stimulate those who are found to be menaced by the beginnings of cardiac or other preventable diseases, so that they may not neglect to secure timely care. The personnel, number, and scope of work of the clinics maintained by the Bureau of Preventable Diseases in the City of New York is so limited as to be utterly incapable of expansion so as to justify the claim that the Health Department is really and efficiently *preventing* the "preventable" diseases. The public must be persuaded to support more clinics and larger personnel, and to make possible the expansion of our preventable disease work so that we will not be limited as at present largely to tuberculosis. The statistical citations previously given show that as much is needed for the prevention of cardiac disease as for tuberculosis. In the last thirty years, the mortality from tuberculosis has been reduced very considerably as a result of improved tenement house laws, improved economic conditions, and of anti-tuberculosis work, while the mortality from cardiac diseases has been increasing, or at least remaining stationary and causing quite as many deaths as are registered from tuberculosis.

### Broad Preventive Work

Although a digression, it is timely to call attention to the obstacles in the way of broadening the scope of the preventive medical works of the clinics of the Bureau of Preventable Diseases which now must unfortunately be confined to tuberculosis work.

This is the era of the promoter. There is hardly a cause or enterprise that can hope to attract and hold public interest without the aid of the promoter or propagandist. This is equally true whether the cause has for its object the alleviation of starvation, the prevention of disease and death, or whether it be an ordinary commercial scheme. The quickening

of the social conscience of a fairly large fraction of humanity in the past several decades, has given opportunity for the development of a group of persons who have a special aptitude for attracting attention to a particular cause in which they may have a temporary or even an abiding and sincere interest. The absorption of the great mass of people in the struggle for existence, in pursuit of wealth, or in shaping a career for themselves, or in other purely personal interests, have made the employment of publicity and promotion devices necessary. The promoters and their appeals have so multiplied, and the high-salaried advocates of schemes for salvation have so frequently fallen under suspicion, that it has become indeed most difficult to arouse interest in causes that may have great merit. This confusion of appeals has unfortunately frequently given the public an excuse for indifference to social needs that are of paramount importance. What is still worse, the pleaders and promoters of public health measures have, like the rest, developed interests that are so narrow and specialized that they have jostled and crowded and trampled upon each other, figuratively of course, in their efforts to reach their respective goals. The public health officer whose functions and interests are comprehensive and of wide scope is prodded and coerced by each of these special pleaders, and he is threatened, if he should make any attempt to link up and solidify the activities in the respective fields of public health work so as to present a solid and unbroken line for attack and defense against the various preventable diseases. The promoters of special movements in public health are frequently as jealous as lovers. The price of their friendship is frequently nothing less than whole-souled absorption in their special field of work.

All hospitals or institutions which are in part or in whole subsidized by the government should be required to render service in the correction of physical defects in individuals found to be affected with conditions which predispose to, or excite, cardiac or other preventable diseases.

### Protect Adolescent Health

Much has already been said that applies to the protection of adolescents, but attention should be called to the need of giving special study to this age group. It is during this period that vital changes are being effected in the human organism.

Not only is this a period when tuberculosis, if latent, is very likely to light up, but disturbances of thyroid function in girls in particular, and other biological changes make it necessary to prevent any addition of mental or physical strain to those who show any tendency toward departure from the normal, or an incapacity to bear such strains as even normal children can with safety endure. The high school curricula should be of such character as to allow for proper education along health lines and for the prevention of any undue physical or mental strain.

For those of adolescent years who are about to enter industry there should be organized some method of vocational guidance and placement that will prevent the entrance into unfavorable industries or occupations for those having cardiac defects as well as other physical and mental defects. Industry as a whole, as well as the community and the individual, would benefit by some official and expert direction and placing of those seeking employment.

### Convalescent Care

Just as it has been found economically necessary and wise to establish and maintain hospitals for the care of acute illnesses, and sanatoria for the care of the tuberculous, so there ought to be established sanatoria and convalescent homes for those recovering from infections or other diseases which predispose to cardiac disease, and for those who are recovering from acute cardiac disease or cardiac breakdown, where the disease is already established. Many cases that lack proper medical and nursing care following acute disease, or during a period of lost compensation, are aggravated and given a downward impetus because of the lack of such care.

### Workshops for Cardiacs

Many cardiac disease patients are under compulsion to be self-supporting, and it is desirable, so far as possible, that they should have some useful occupation. The studies that were made during the war in connection with reconstructive work should be carried forward by an official body in cooperation with medical representatives, to determine with even greater definiteness than has already been done, the various types of work which may be suitable for those suffering from various kinds and degrees of cardiac disease. Official machinery may be established within the employment department of the State Indus-

trial Commission and of similar bodies to give preference for employment in suitable kinds of work to those having cardiac disease, and the effects of such work ought to be controlled not only by thorough and sufficient factory inspection to insure proper industrial environmental conditions, but it ought to be checked up by industrial or health department physicians, and by the dispensaries and hospitals under the control of private institutions or of the Department of Health.

### A Joint Responsibility

The cooperation of merchants and factory owners ought to be secured to this end, by their representation on the employment agency boards, as well as on the medical boards, the latter being requested to give expert advice with reference to the conditions of employment of cardiac patients. Those forms of labor which are suitable for cardiac patients and which are contracted for by the city government ought to be conducted in workshops maintained by the city for the employment of cardiac patients under proper medical supervision. The various institutions and offices of the city government requiring certain kinds of supplies or forms of work, could, so far as practicable, have such services performed by cardiac patients working for the city under the supervision and direction of its medical experts.

Encouragement should be given to the establishment of workshops for cardiac disease cases by private organizations, so that work of a suitable character done under proper medical supervision, could be performed by those having cardiac defects. This has been demonstrated as being practical and of value in the vocational reconstruction of tuberculous individuals.

While the sentiment against permitting industrial work to be done at home has been very strong of late, encouragement should, however, be given to the establishment by private agencies or organizations of home work of suitable type to be done by cardiac patients who are confined to the home by nature of their physical defect. Such work should likewise be done under proper medical supervision and control.

There are many workers employed in establishments where the humidity, as in paper making, is in marked excess; or, where the workers have to stand in puddles of water, as in laundries; or, where they are employed in an environment in which the temperature is extremely low, as in stor-

age houses; or, where as in steel mills and in numerous other employments, the heat is most intense. All of these workers, as well as those who are exposed to severe muscular strains or to other factors conducive to marked fatigue, as well as those who are exposed to a variety of toxic chemicals, gases, vapors or fumes must be adequately protected, so as to prevent the development of serious cardiac defects or other serious preventable diseases. Time will not permit of the enumeration of the thousands of workers who are daily exposed to lead, mercury, and arsenic poisoning, to instance but a very few of the many toxic agents which may cause a primary or secondary damage to the heart and vascular system. Factory medical inspection of the most thorough kind which will reach into every factory and industrial establishment, and which will appraise the harmfulness of the various industrial factors in their effects upon the heart and other parts of the body, is needed. From such inspections there should follow the formulation of standards and the definite prescription of protective devices which will serve to give the proper degree of temperature and humidity, and which will eliminate needless exposure to toxic agents and dusts, and eliminate the various factors which strain the muscular system and tend to produce cardiac or other preventable diseases. The provision of adequate medical care for factory employees is absolutely essential to safeguard their health, and the examinations in factories should be of the same character as those in the various preventive clinics and dispensaries which have already been outlined, for the purpose of making periodic medical examinations to discover preventable cardiac and other diseases, and to follow up such persons until they have been persuaded to place themselves under proper medical or surgical care.

#### Short Day and Rest Periods

The short work day should be encouraged on public health grounds wherever severe muscular exertion or other factors producing marked fatigue may be found in the industrial environment. Also, frequent rest periods should be advocated by the public health authorities under similar conditions, because wherever they have been tried, they have been found to increase efficiency, conserve health, and materially reduce the frequency of illness, accidents, and absenteeism.

One rarely encounters the opposition that was formerly voiced to the granting of vacations to employees. Such vacations may be counted as of immediate tonic value in preventing or correcting the effects of fatigue and over-exertion and of physical and mental strain, which play such a vital part in the development of cardiac affections. Education here should be valuable, not only to persuade factory owners to grant vacations so as to permit recuperation from physical or mental strains which may be conducive to cardiac and other defects, but they should also aim to instruct those obtaining such vacations how properly to utilize them, and so to conduct themselves as to derive a maximum of benefit from them.

#### Mind and Physiology

We have learned much about the reaction of mental strain, worry, rush, and bustle, and unrestrained zeal and ambition, in their reaction upon the glandular structures currently described as the "endocrine bodies," and the far reaching effects which they produce directly or indirectly upon the vascular system and upon the heart. Mental strain and worry among those in whom cardiac defects are already established, has been recognized by every clinician as having a tendency to produce serious aggravation of the patient's physical condition. In view of the effects of such mental strain in predisposing to the development of secondary cardiac damage, and in view of the pernicious effects which such mental strains exert in cases where heart diseases already exists, it is extremely important to carry a special message of warning to be imparted quite early in life, especially to those whose family history gives an indication of a tendency toward development of diseases of the heart and of the circulatory system.

#### Serve Cardiac Housewives

It is suggested that in view of the fact that a fairly high mortality has been found to exist among housewives at a fairly early age group, and in view of the fact that a relatively large percentage of these housewives have either acquired such cardiac diseases in childhood following infectious disease, focal infection, or other causes, or have developed them as the result of exposure to industrial conditions, or the strain of child-bearing, it is extremely important that the pressing and inescapable burdens of housekeeping and caring for the families be lightened by pri-

vate organizations so far as possible. This can be done by sending into the homes of housewives suffering from cardiac disease, paid day-helpers, cleaners, or special domestics to give part time or full time service in such homes, so as to relieve such housewives of the necessity of overtaxing their reserve capacity by scrubbing, washing or other strenuous labors. In time of need there should also be not merely bedside nursing service, but a nurse's assistant or "practical nurse" who should give continual bedside care and such attention to household duties as may be needed during the time the housewife is suffering from any intercurrent illness or loss of cardiac compensation.

#### Public Health Institutes Held in Twenty-one Cities

A series of one week public health institutes to be held in twenty-one principal cities over the country and extending over the first five months of 1922 will be given by the United States Public Health Service in cooperation with state and city departments of health and related health organizations. With the exception of the Chicago and Pittsburgh institutes, which are devoted exclusively to a consideration of venereal disease problems, the institutes will include lectures on tuberculosis, child hygiene, nutrition, communicable and non-communicable diseases, industrial hygiene, mental hygiene, sanitary engineering, medical social work and administrative problems. Visits to clinics, hospitals and health centers have also been arranged. At approximately eight institutes special conferences for women not professionally engaged in public health work will be held under the direction of Dr. Rachele Yarros.

The institutes are open to health officers, physicians, teachers of hygiene, nurses, social workers, and members of various health organizations. No tuition fee is charged. The faculty is comprised of leading health workers distinguished in their respective fields, supplemented by staffs of health departments, medical schools and local health agencies.

Institutes have been scheduled for New Orleans; Columbia, S. C.; Dallas; Birmingham; Memphis; Louisville; Indianapolis; Pittsburgh; Jacksonville; Detroit; Chicago; Minneapolis; Hartford; Portland, Ore.; Kansas City, Kans.; Spokane; Newark; Albany; Denver; Washington, D. C.; and Atlanta.

# Traveling Chest Clinics in Wisconsin

By T. L. HARRINGTON, M.D., MEDICAL DEPARTMENT, WISCONSIN ANTI-TUBERCULOSIS ASSOCIATION, MILWAUKEE, WIS.

**I**N MARCH, 1919, the Wisconsin Anti-Tuberculosis Association instituted a series of traveling chest clinics in the small communities of the state. Never in the thirteen years of active work of the Association was a more important or far-

reaching piece of health work undertaken, than was begun with the first free chest clinic. In these two and one-half years (March, 1919, to September 1, 1921) 186 clinics have been held and a total of 9,088 cases have had careful chest examinations.

During the first year of this work, the Wisconsin Anti-Tuberculosis Association bore the entire expense of these clinics. The demand for clinics became so great, and the financial burden became so heavy that it was necessary to divide the expense with local agencies. The Red Cross, the local Anti-Tuberculosis Society, occasionally a woman's club, and, in one or two cases, the city council assumed responsibility for about one-half the expense.

## A Real Health Inventory

The examinations, however, are more than chest examinations. The examining physician makes careful inspection of the eyes, nose, teeth, tonsils, examines for evidences of adenoids and goiter, and finishes with a bare chest examination, which includes careful examination of the heart and lungs. Before the examination is begun by the physician, a careful history is taken on a specially prepared blank. This history sheet gives the usual history data, and in addition both the present weight and

the normal weight of the patient, together with the temperature and pulse. If the history sheet shows that the patient comes from a family in which there has been an active case of tuberculosis, the question of "contact" or "no contact" is carefully

noted. When there has been contact with an active case of tuberculosis, it is important to know the age of the patient at the time of contact and the number of months or years during which the possibility of massive infection continued.

The history sheets with the record of the physicians' examination are made in triplicate and, at the completion of the examination, one copy is given to the patient in order that he may have the record and show it to his physician, one copy is turned over to the public health nurse for follow up work, and the third copy

is retained for the files of the Wisconsin Anti-Tuberculosis Association.

When a clinic is to be held in any community one of the social workers of the Association goes into this community a few days before the opening date of the clinic to make all necessary preparation. This includes the securing of a building with a suitable waiting room, room for taking of histories, etc., and a private room for each examining physician. It is customary to use rooms in the Court House, public library, post office, or other public building because the discovery of early cases of tuberculosis is a public function. All the nurses of the community are drafted into service for the clinic days. In addition to the nurses it is usually necessary to secure the aid of several additional volunteer workers who act as history takers at the clinic. The Social Worker, with the assistance of the county or community nurse, digs out from the records of the Health Officer or the County Clerk the names and addresses of all persons who have died of tuberculosis during the past four or five years. The families of such persons, and of all other contacts that can be discovered, are visited and urged to attend the chest clinic. Schools and factories are visited and short talks are given on the early symptoms of tuberculosis and the value of periodic physical examinations.

## Reaches the School

The School Nurse is urged to bring for examination all children that are 10 per cent or more underweight. Publicity for the clinic is secured

Making sure that the clinic trunk will ride safely to the next town.

With traveling bags on the running board and trunk and platform scale in the rear, the clinic is ready for the road.

through the local papers, and through posters and dodgers that are sent into the surrounding rural districts. The result is that on the opening morning of the clinic shortly after eight o'clock, the patients begin to come, and usually continue to come until late at night. The examining physicians, by beginning the examinations promptly at nine o'clock and working over long hours are each able to examine an average of about thirty patients per day.

The results of these examinations are most interesting and instructive. Of the over nine thousand patients examined 18 per cent were found to have tuberculosis in some form, 20 per cent had diseased tonsils, 15 per cent had badly decayed teeth, 6.7 per cent had heart disease, and 6.3 per cent had simple goiter. In every case in which disease in any form was discovered, the patient was advised regarding the nature of the trouble and the course of treatment required to afford the best chance for recovery. In most cases in which a positive diagnosis of tuberculosis was made, sanatorium treatment was advised and in many cases before leaving the clinic all arrangements were completed for the patient's entrance into the sanatorium. More than 50 per cent of all patients examined were referred to the family physician for consultation and treatment. Large quantities of health literature have been distributed at each clinic and as this literature is specially prepared to meet the needs of those who come to the clinic, it is certain that great good comes from the custom of supplying each patient with printed information to fit his case.

It is interesting to know that when the clinics were first started an occa-

sional member of the medical profession was disposed to criticise the clinic on the ground that it was an interference with the regular work of the practicing physician in that community. As these men watched the work of the clinic, and as members of the profession visited the clinic and spent considerable time watching the technic of the exam-

nity in which a clinic has been held found that during the weeks following the clinic a considerable number of patients came to the office, bringing a history sheet which showed that they had been instructed by one of the clinic physicians to go to the family physician or to a specialist for further study or for treatment.

These clinics have grown in popu-

In one corner of the waiting room patients are weighed and temperature and pulse taken.

iners, the feeling of antagonism changed to a feeling of gratitude for the service that was rendered the community. It is gratifying to know how the profession as a whole has endorsed this advanced step in social medicine. The clinic physicians have been specially trained in chest examination, and have made a special study of tuberculosis. The result is that the general practitioner visiting the clinic has been able to pick up many points in the newer methods of chest diagnosis. It has also been observed that every practitioner in the commu-

larity as the nature of the service becomes known in the communities. During the last year it has been the rule that from 10 to 25 per cent of those coming for examination were turned away because the numbers are so great that it is usually impossible to make all examinations during the short stay of the clinic. While it is unfortunate that a considerable number of patients who desired a chest examination are turned away without this examination, it has its fortunate side in the fact that those responsible for the clinic in the locality feel the necessity of another clinic in the near future, and in a considerable number of cases a second clinic was scheduled before the clinic workers left the town.

### The Periodic Examination

Another advantage comes from the fact that a number of those who failed to secure an examination, and a number of others whose attention is directed to the value of periodic physical examinations, visit a private physician for such examination. And in the final analysis it will be the medical profession that must meet the problem of discovering the cases of tuberculosis while still most curable.

The story of two patients who were examined at a recent clinic may interest the readers of this article.

Volunteer workers are pressed into service in the taking of histories of the patients examined.

The examination includes inspection of the nose and throat as well as the chest.

One was the wife of a farmer who drove some twenty miles to secure an examination at a clinic. She had seen the publicity in the local paper, and as she had not been well since the birth of her last baby, she decided to have an examination. This little woman was the mother of six children, the oldest eleven and the youngest a baby at breast. The examining physician pronounced her an active case of tuberculosis. When she was told that her best and surest chance for recovery was to be found in sanatorium treatment which might require a stay of from one to two years in an institution, she broke down crying, and between her sobs said she could not leave her babies. The physician reasoned with her, telling her that to remain with her children meant sure infection for all of them, and the chances were that one or more of her six children might receive sufficient infection to cause the death of the child. After two or three minutes this little woman wiped away her tears and said: "If that is true, I will go to a sanatorium."

### The Will to Health

We have read much of the heroism of our boys who went into the trenches at the Marne, at Chateau Thierry, at Belleau Wood and at other places in France where they faced the withering fire of the trained German soldiers. I doubt if the courage of any of these splendid youths was

greater or was more deserving of praise than was the determination of this little mother to leave her six babies for a year or more and go to a sanatorium, not so much to save her own life, but to save her babies from this infection.

The following is an entirely different type of case: A girl, growing into womanhood, was a student in the Normal school in one of the cities in which a chest clinic was held. A brother had died of tuberculosis some four or five years before. For a number of months this girl had been nervous and losing in weight. She was unable to do her required school work. She made up her mind that she had consumption, and yet she dreaded to know the truth. When her examination was finished and the ex-

amining physician told her that her lungs were perfectly sound, a sigh of relief escaped her, and an expression of joy spread over her countenance. A great weight had been lifted from this girl's mind, because she found that her worries were without foundation. A little advice from the examining physician permitted this girl to return to her school work in an entirely different mental state, and with the ability to put her mind on her studies. She soon caught up to her class and regained the lost weight. It is sometimes almost as important to assure a patient that there is nothing the matter but worry as it is to point out to another patient the nature and location of a diseased organ that has been causing a gradual decline in health.

## Women in Medicine

BY OUR SPECIAL CORRESPONDENT

RECENTLY we made a little journey to the haunts frequented in our young medical days. Many places were no longer recognizable: physical and functional changes had made of them entirely different institutions. As we pondered the passage of time, naturally there was the pang of personal regret that such things never were in our time. Ye good olde days are passed.

Not the least striking change in all the medical institutions was found in the changed personnel of the places: Women, women everywhere; feminism gone rampant in medicine. Where one woman held sway in ye good olde days, now twenty women are busy pounding typewriters, taking dictation, and interviewing patients. The dispensaries were crowded with social workers. In one large dispensary handling between three hundred fifty and four hundred patients a day, there seemed to be a legion of women, and every one who came directly in contact with the patients was a trained social worker. As the trained social worker these days is apt to be a college graduate as well, it can only be conjectured what results educated feminism may be able to accomplish for medicine! At one big hospital where the majority of social workers are voluntary contributors of their service, the old wooden floors seemed to be just full of women.

In the laboratories the occasional woman student of other times is now an accepted part of the curriculum

and a given number of women are accepted in each course. Women research workers are frequent; women interns are not uncommon.

Medicine in this country opened up to women when a woman benefactor to a new school made the admission of women a *sine qua non* of her gift. Since then what strides feminism has made! Yet one reflects that the object of medical education is really to train physicians to heal the sick, to prevent illness. In point of fact in actual life this means not only the practice of a science, it means also conflict, competition. Still the field of women in practice is limited. As most men do not want a woman physician the field of women's practice is automatically shifted to gynecology, obstetrics, and pediatrics, and competition for them is unfair. We do not have statistics of women in practice. We do know that the general impression is that only the minority make good as practitioners. In the laboratory sciences or in clinical research the names of many women figure prominently.

How many women marry and then stop all practice of medicine? We would like to see some statistics covering the whole question of women in medicine. But while waiting for these figures to come in and while speculating on the result, we want every first class school to open its doors to women as to men. The advance of the woman movement is too logical to be resisted. We should open our gates and see what happens.

## Royal Air Medical Service Rules

THE Royal Air Medical Service Rules to improve respiratory and circulatory efficiency are formulated by Wing Commander Martin Flack, Royal Air Force Medical Service, in the Milroy lectures recently delivered before the Royal College of Physicians of London, on "Respiratory Efficiency in Relation to Health and Disease." This system of ten exercises he has elaborated for the purpose of producing circulatory and respiratory fitness, the work being based on physiological principles and observations made in the training of fliers. In the performance of these exercises Commander Flack lays stress on the great importance of the contraction of the diaphragm at the initiation of inspiration, protruding the "pit" of the abdomen together with a movement of the lower ribs, full inspiration being obtained by a wave-like movement spreading from the lower ribs to the upper part of the chest, and on no account should the upper part of the chest be expanded first. Expiration is accomplished by the contraction of the muscles of the abdomen and of the lower part of the chest. The exercises are here given:

(1) In bed. (a) Lying flat, inhale to the fullest extent, at the same time raising the hands above the head in a natural "stretching" motion. (b) Exhale to the utmost extent, using the abdominal muscles forcibly to press out as much air as possible from the lungs, at the same time carrying the arms to the sides. Repeat five times.

(2) Using the weight of the bed clothes turned down to the hips as a means of keeping the legs down, raise the body from the hips and bend forward as much as possible, at the same time breathing out forcibly to the fullest extent, then slowly return to the lying posture, inhaling deeply meanwhile. Repeat five times.

(3) (a) Using the bed clothes as before, from the lying position raise the trunk, with the hands by the sides, through an angle of 45 degrees, then twist round the trunk upon the hips, keeping the legs flat and endeavor to make the forehead touch the bed, meanwhile exhaling forcibly as far as possible. (b) By a reverse movement assume the lying position, inhaling deeply meanwhile. Repeat five times to right and left sides.

(4) (a) From the lying position, flat on the bed, with the hands clasped behind the head, raise the legs from the hips, carrying them as far over the head as possible meanwhile. (b) Lower legs slowly to the fullest extent, meanwhile exhaling deeply and forcibly. Repeat five times.

(5) Out of bed. (a) By a "stretching" movement raise the arms slowly and strongly forward and upward,

then lower them sideways until they are in line with the shoulders, which are well thrown back, meanwhile inhaling to the fullest extent. Brace up the muscles of the abdomen and all the accessory muscles of inspiration. (b) Keeping the body as upright as possible, carry the arms forward until they overlap and hold sides of trunk; expire meanwhile to the utmost extent, working specially the lower chest and abdominal muscles. When in the position of full expiration brace up all muscles of lower chest and abdominal wall. Repeat five times.

(6) (a) With the feet about 18 inches apart (or other comfortable distance, which may be gradually decreased as proficiency is attained) carry the arms forward, upward and backward, inhaling meanwhile to the fullest extent. (b) Bend trunk forward and full downward, carrying the arms between the legs to touch the ground with the fingers as far as possible behind the feet, meanwhile exhaling to the fullest extent. Repeat five times.

(7) With the feet about eighteen inches apart (this distance may be decreased as proficiency is attained) and arms raised sideways and in line with the shoulders, bend the trunk to the left (right) until the left (right) hand touches the ground, keeping legs

straight, meanwhile breathing naturally or holding the breath. Repeat five times to each side.

(8) (a) With the feet as above, carry the arms forward, upward and backward, inhaling meanwhile to the fullest extent. (b) Turn and at the same time bend the trunk to the left (right), and touch the ground on the outside of the left (right) foot, expiring meanwhile to the fullest extent. (c) Stretch trunk upward to upright position, inhaling meanwhile to full extent. Repeat five times to each side.

(9) Inhale as fully as possible, then exhale sharply to the fullest extent, and, with the chest and abdominal muscles, alternately forcibly contracting and relaxing. Repeat two or three times.

(10) Stationary running; shadow boxing; shadow skipping; rhythmic balancing exercises; jumping or any other form of exercise preferred by the subject until out of breath.

These exercises take about ten minutes to perform and should be followed by a tepid or cold bath and a brisk rub down. They are particularly useful for those engaged in sedentary occupations and will enable them to engage in open-air exertions without undue fatigue. They are to be especially recommended as requiring no special apparatus.

## Records on the Healthiest Year

NINETEEN twenty-one has well earned the distinction of being "the healthiest year" judging from the figures supplied by health departments, life insurance companies, and vital statisticians. New York City showed a decline in the general mortality rate from 12.93 in 1920 to 11.17 per 1,000 in 1921. Infant mortality was reduced from 85 to 81.1 per 1,000 births and the death rate of children under five years from 30.8 to 23.8. Chicago which has advertised itself as the healthiest of the country's large cities reported a death rate slightly under 11 per 1,000, a decrease in about four thousand deaths as compared to 1920.

A report of much significance is that of thirty-seven leading American life insurance companies which transact about 80 per cent of the life insurance business and cover twenty-seven million persons. The figures indicate a reduction in the death rate from 9.80 per 1,000 in 1920 to 8.24 per 1,000 for the first ten months of 1921. A notable decrease in tuberculosis and pneumonia—almost 40 per cent in the latter—and the few fatalities from influenza are mainly responsible for this steady

decline. Whereas tuberculosis was responsible for one out of every four deaths ten years ago, it now causes only one in nine deaths.

Not everywhere can this decline be noted. Homicides, suicides and deaths caused by automobile accidents are on the increase, the two former probably due to the stresses of post-war reactions, and the last to individual carelessness and inadequate policing. Cancer, Bright's disease, cerebral hemorrhage and organic diseases of the heart evidence little or no decline according to mortality records.

Gratifying as these records must be to health workers, any relaxation in the present efforts of disease prevention must be assiduously avoided. The low mortality rates which prevailed in this country during and immediately following the war were explained in part by the general prosperity which pervaded the land, accompanied by improved living conditions of every character. A crucial year is 1922, with unemployment at its height and low wages and poverty much more extant than in recent years. Can these handicaps be overcome so as to permit an uninterrupted decline in the mortality rates?

# Plague Excluded from the Canal Zone

BY OUR LATIN-AMERICA CORRESPONDENT

THE geographic position of the Panama Canal is at once its weakness and its strength in its relationship to the international spread of disease. Ships come to it from all parts of the globe; they moor at its docks; they discharge and

the Isthmus, since plague there would constitute a health hazard to uninfected ports only secondary in importance to the menace it would exercise against the health and prosperity of the Canal itself.

The quarantines at Cristobal and

measures for the prevention of the disembarkation of rodents and the fumigation of vessels. In this way they are, so to speak, lymphatic glands which remove disease from the commercial circulation and destroy it for the protection of the body politic. In this connection the following circular issued by the Panama Canal Zone executive offices, is self explanatory:

Balboa Heights, C. Z.,  
October 12, 1921.

To Owners, Masters and Agents of Vessels Arriving At Panama Canal Zone Ports, and All Others Concerned:

Bubonic plague is now prevalent in many of the seaports of the world. It is of the utmost importance to shipping interests that every possible measure be taken to prevent the spread of this disease to other ports and it is imperative that the Panama Canal, an international highway, continue free of plague.

To accomplish this, it is necessary to prevent the migration of rats by ships and to this end the Quarantine Regulations of the Panama Canal will be strictly enforced. Ready compliance with these regulations and hearty cooperation with the quarantine officers will react to the benefit of shipping interests, by the protection of the health of ships' companies and the prevention of expensive and vexatious quarantines, here and elsewhere. The regulations now in force are the minimum compatible with safety and as such must be obeyed in all particulars. Arriving vessels will observe the following regulations un-

The Panama Canal rat-guard. The strap iron reinforcements give it rigidity and hold it perpendicular to the line. The lashing is a permanent part of the guard and the internal half cones make it fit any line accurately. It is easily and quickly applied and light enough to facilitate handling.

receive cargo and passengers; they pass through the locks and to some port there to receive cargo and passengers which perchance may contain the living organisms of disease.

The Canal Zone and the terminal cities in the Republic of Panama are not exporters of epidemic disease. They are not infected. With the exception of bubonic plague and the sputum borne infections they have little to fear from the importation of disease. The *Aedes* index is so low that yellow fever, if introduced in infectious form, could not spread. The hot humid climate is inimical to lice and therefore to typhus. Cholera does not spread greatly in a flyless environment having a good water supply. In fact the health vigilance exercised by the American Government is such that the Panama Canal Zone is safe to itself and the outside world.

Plague though, is an omnipresent danger. It is entrenched in many of the ports having commercial contact with the Panama Canal and the greatest care must therefore be exercised lest the infection be landed on

Balboa carry on the work of boarding ships and inspecting passengers, crew and cargo. They also enforce the

Bent rat-guards which do not fit tightly or stand perpendicular to the mooring line offer very little hindrance to the landing or embarkation of rats. At night gangways should be raised or guarded by a watchman. Every means of rodent ingress and egress should be rat-guarded.

der penalty of being placed in quarantine and moved from the docks or fined, or both.

Metal rat guards not less than three feet in diameter will be applied to all mooring lines. They must be in good repair and must fit the lines accurately. They must not overhang or be nearer to the dock than six feet. Ships must be breasted off at least six feet. When exception is made to this rule on account of short cargo booms, the vessel will be immediately breasted off when not working.

Save-alls, catch-alls, hose and all communications with the dock except gangways and properly rat guarded lines, must be disconnected at night and when the ship is not working. Gangways must be raised at night or well lighted and guarded by a watchman.

Vessels should be fumigated frequently for the extermination of rats and other vermin aboard. All arriving vessels, except those not discharging cargo or passengers at Canal ports, which have not been satisfactorily fumigated within three months, will be fumigated. Vessels habitually using Canal ports exclusively (tugs, dredges, barges, etc.) will be fumigated at least every six months.

Respectfully,  
M. L. WALKER,  
Acting Governor.

To assist ships in complying with this order there is an adequate supply of rat-guards at all docks and these are loaned without charge to vessels lying at docks. A special guard has been developed for this

purpose. It is thirty-seven inches in diameter and is constructed of No. 18 galvanized iron. Its rigidity is maintained by six metal straps 1/8-inch by 3/4-inch by 24 inches. These turn at right angles at the centre where they are riveted to a half-cone of galvanized sheet iron in order to make the guard fit any line. One of the braces is turned over into a ring

guard always stand perpendicular to the line. The guard is painted red to prevent rusting and to facilitate the rapid inspection of docks to ensure the careful rat-guarding of all connections with the shore.

Ships are breasted off by floats. At Balboa these are held in place by chains which are counterweighed and run over pulleys. This is necessary

Unguarded water hose are a constant source of danger. They should be disconnected or rat-guarded when not in use.

for the attachment of a 1/4-inch lashing line which is spliced so as to make it a permanent part of the guard. The method of attachment makes the

because of the high tides on the Pacific side. At Cristobal there is only a 10-inch tide so ordinary floats which are moved about by the dock force, as needed, are used.

Ships are fumigated by sulphur and cyanid. The results obtained are illustrated by the following table:

S.S. "COLON"	
Date fumigated	Rodents recovered
March 21, 1920.....	181
November 13, 1920.....	90
June 27, 1921.....	119
September 21, 1921.....	63
December 12, 1921.....	31
S.S. "HUASCO"	
June 12, 1919.....	752
September 12, 1919.....	76
January 17, 1920.....	20
May 21, 1920.....	32
September 25, 1920.....	22
February 21, 1921.....	13
May 31, 1921.....	31
September 1, 1921.....	46

The destruction of rodents and other vermin has proved so satisfactory that owners, agents, and masters of vessels welcome fumigation and frequently request it before the expiration of their certificate. As a matter of fact, the shipping interests have cooperated wholeheartedly with the Quarantine Division in the enforcement of the governor's circular quoted above. *Nauticus*, a marine journal published in New York, carried in its issue of November 19, 1921, a cartoon which illustrates how good naturedly the anti-rodent operations are regarded. Everyone has a part in the game and laxity is not tolerated anywhere.

THE PASSING SHOW

This cartoon, which appeared in "Nauticus" demonstrates the way in which the shipping interests view the anti-rodent campaign.

## The Health of Insured Groups

**A** NEW and powerful incentive for the promotion of health has developed through the growth of insurance among the working people of this country. That incentive is nothing less than the combination of economic and humanitarian forces. Either of these forces by itself is powerful but the two working together should be irresistible.

The insurance carriers measure the risks of disease and death and fix their rates accordingly. In earlier times little account was taken of preventive methods. Applicants were examined, the physically weak were rejected, and the companies assumed the risk on the others. Then some optimistic and far sighted insurance officials saw that it would pay to reduce sickness. Next came the insurance of whole groups of employees without physical examinations. Preventive methods were emphasized by this wholesale insurance, the more so because of the risks of loss from epidemics in a single plant. The insurance company acquired an economic interest in the working conditions, sanitary surroundings, medical and health care of workers. The employer likewise acquired an economic interest because he paid all or the major part of the premium. Each worker acquired an economic interest in his fellow employee's health because the workers were all insured and had a direct interest in the success of the insurance and in its cost, particularly if they paid part of the premium. All of these groups

had their attention drawn sharply to the importance of health.

The results are beginning to be seen in health activities on the part of insurance companies, employers, and employees to promote educational and other campaigns for better health. The promotion of group health through this new development should be one of the most effective methods of the future in the effort to imbue the rank and file with the desire and incentive for improving health.

## The Value of Periodic Medical Examinations

**T**HE most striking testimony yet offered to the value of periodic medical examinations has recently been furnished by the Metropolitan Life Insurance Company, which for more than seven years has been offering the life extension institute service without cost to its policyholders. Approximately six thousand persons were examined under this plan in the years 1914 and 1915 and the after history of this group was observed up to November, 1920, for an average period of five and one-half years per person. The expected mortality for a group of the class and age concerned would have amounted to 303 deaths, but actually only 217 deaths occurred,—a saving of 28 per cent.

The number is small but the difference is so marked that it cannot reasonably be attributed to chance, and the company estimates that the sum of forty thousand dollars spent in these medical examinations has effected a saving in mortality in excess of \$126,000. Results of this kind should be of the greatest assistance in furthering the movement for systematic medical examination, which offers the only hope of effective control of the degenerative diseases of adult life.

## The Industrial Menace of Noise an Important Issue

**I**N THE very general improvement in the factory sanitation, industrial surgeons have made a successful and beneficial warfare against fatigue, bad ventilation, poor lighting, and dangerous machinery. The employee is protected against contagious diseases; his working postures have been studied and corrected; he is supplied the means of maintaining cleanliness; he is taught the value of his health and the means of conserving it. To date, however, too little attention has been paid to the very deleterious effects which loud and continuous noise exercises upon the health of industrial workers. Not only does the continuous exposure to noise produce fatigue far

more quickly than muscular effort, it also produces an irritability and interferes with concentration in such a way as seriously to handicap efficiency. This lowers output and increases production cost. These effects are not remarkable when one considers the thousands of auditory stimuli which daily impinge upon the brains of workers in the noisy trades.

Unfortunately, many factory surgeons regard the din of factories as wholly inevitable and take no steps to its reduction except perhaps to advise the wearing of ear plugs or some other individual protective device. In some factories the introduction of the electric drive has had a quieting effect and in a broad way it is recognized that most noise represents lost motion, but there has been no systematic attempt to eliminate all unnecessary sound from industry.

The one-lunged, giraffe-like automobile of a few years ago was an animated cacophony. The modern car is the silent embodiment of power. The demands of the general public have produced this result. In a similar way, industrial surgeons can and should undertake seriously and systematically the muffling of factories. In this they should seek the cooperation of both engineers and operatives.

Prof. H. J. Spooner in his Chadwick lecture presented in this issue of *THE NATION'S HEALTH* has raised another interesting point in this connection. He proposes that there be fixed a limit of permissible noise, in other words, to create a sound unit. This of course is not easy, but it is logical. Perhaps the standard should be the necessity of the sound in question, but there are noises connected with the operation of factories which are now regarded as necessary and unavoidable which with the mechanical improvement in machinery may be eliminated.

---

### Ohio Eliminates Red Tape and Gets to Work

CARING for the crippled child has received but little thought on the part of public health officials in the past. Many states through workmen's compensation and other measures are providing for the rehabilitation of the industrial cripple, and the Federal Government has developed extensive machinery for the treatment and re-education of disabled former service men. But the crippled child is not the victim of our industrial system, nor is his handicap the result of military service, so that neither the appeal of economic breakdown nor that of patriotism can be employed in behalf of these unfortunates.

Elsewhere in this issue of *THE NATION'S HEALTH* appears an article on the Ohio plan for solving

the problem of the crippled child, written by Edgar F. Allen, a business man of Ohio, who, with the aid of other business men of that state, has conceived and developed a scheme for caring for the crippled child that at once invites the respect and challenges the consideration of hospital and health workers everywhere. Backed by forty-six Ohio Rotary Clubs, which constituted themselves into the Ohio Society for Crippled Children, legislation has been enacted providing first for treatment at state expense of all crippled children, and second the mandatory establishment of special schools and classes for crippled children, the state allowing three hundred dollars per child.

The significant feature of the Ohio plan is the handling of the problem on a district basis—nine districts already having been established—so that the facilities are brought to the child and not the child to the facilities. Experience has proved the one institution plan a failure since 90 per cent of the children come from within a radius of forty miles. Another point of interest is that the state will subsidize private and general hospitals which have certain standards of equipment and personnel rather than erect special state hospitals. The sponsors of the plan believe that better results will be obtained and much red tape eliminated by means of this arrangement. Follow-up work by trained workers is another important element in the program.

Two years ago Ohio had a total of 110 beds for crippled children; today it has six hundred beds and more are expected. The twelve thousand crippled children in Ohio will soon be receiving their long needed attention. Public officials and business organizations in other states may well emulate Ohio's example.

---

### On the Writing of Medical Editorials

AN EDITORIAL is supposed to represent the crystallization of the policy of the publication in which it appears. Its function is to discuss in a broad way some topic of interest to readers, to present the pros and cons of an argument, and to debate them to a definite conclusion. It is to be a signboard to thought, a direction flag toward advancement. It must combine the qualities of clarity, brevity, timeliness, and frank courage. It does not "say it with flowers," it tells it with a wallop.

The average medical editorial does not do these things. There seems to be a sort of mental hazard about discussing freely and frankly the big problems which confront us as a profession, a shrinking from writing boldly about the great evolution which we are now undergoing, a fear

lest somebody's feelings be hurt, a conservatism which will accept only the copper of thought, lest it turn out to be a counterfeit. Hence medical editorials as a rule follow a safe middle-of-the-road policy, filling space with noncommittal, invertebrate statements which influence nobody.

It is much easier to write abstruse discussions of highly technical matters than it is to take a definite stand on a moot subject like health insurance. Almost anybody can read over a laboratory paper and produce a re-hash editorial, but it takes thought and time and abdominal content to thresh out the new adaptations of medical teaching and the socialization of medicine.

Perhaps, though, there are some good reasons for this. Medical journalism is as yet a relatively unexplored field, despite the fact that medical journals have been published for nearly two centuries. Possibly this arises from the fact that the journals which are owned by societies are afraid of the organization, while those which are privately owned fear the advertisers. Very few medical editors adopt their career as such in youth and rise to the sanctum by application and training, and truth to tell, many lack the broad gauge viewpoint and wide knowledge which must go into the direction of a really good medical journal. Too frequently they are unsuccessful practitioners or men whose bent is largely political, a state which in some instances is fostered by the old system of making the secretary of the society also the editor of its journal. Sometimes a medical editor is not even a physician and he is therefore without a broad background of knowledge by which to form judgments. Too frequently the editor is a busy practitioner who accepts without question the papers which are submitted for publication, runs the propaganda fillers which he receives from various agencies, prints the advertisements brought in by the advertising agent, turns the proofreading over to the office girl and once a month dashes off a hasty noncommittal, innocuous editorial. His clientele has asked for whale and he has given them jellyfish.

Of course there is a good deal more to medical editorship than the writing of editorials. A lot of study of books and magazines and men goes into it. The ruthless rejection of compiled articles written on a typewriter which has lost its quotation marks; the recognition and stimulation of potential genius; the reading of the times aright; the repression of fads; the perpetual combat of charlatanism both without and within the medical profession; the constructive reviewing of books; the collection of news; these and a hundred more components go into the job being a good medical editor. To do these things well requires a certain

type of mind and a very thorough training. Medical editors are not born, they are made,—usually by accident. At present, there is no regularly established way of going about getting to be a well trained medical editor. There is of course the custom of drifting into it, or one may get his friends in the state society to elect him to the position. This latter method has a peculiarly fatal effect on medical editorials, since a part of such an editor's effort at holding his job is to lacerate no sensibilities and to stand in with the crowd in power. This throws more light on the safety first type of editorial which characterizes most medical journals.

Is it not about time to recognize medical journalism as a distinct brand of literary effort and to provide in our universities courses which will lay the foundation for broad-minded, courageous medical editorship? Within a generation such a policy would change the whole face of medical journalism and would work tremendously to the stimulation and advancement of medicine.

### Nems and Calories as Measurements of Food Values

THE visit to America of Professor Clemens Pirquet of the University of Vienna has been notable for several reasons. Professor Pirquet has been delivering the Silliman lectures at Yale and has spoken at many of the other large universities of the country; and his intimate knowledge of American conditions, dating from his membership in the faculty of Johns Hopkins University some years ago, combined with his charming personality, has made him an unusually happy envoy of the period of renewed cooperation with the scientific world of Central Europe. Above all, however, Professor Pirquet's addresses have helped to call attention to the interesting developments in the large scale organization of dietary hygiene which has been necessary in connection with the post-war reconstruction problems. During the war Dr. Pirquet took a leading part in the organization of the food supply of the Austro-Hungarian empire and for the last few years he has applied his technical knowledge and executive power to the direction of the work of the American Relief Administration in Vienna and in the neighboring countries.

The main essentials in the Pirquet system<sup>1</sup> are two: the estimation of dietary needs on the Pelidisi system, and the measurement of food values in nems instead of calories. The Pelidisi system rests on the assumption that a certain relation between the weight of the individual and the sit-

1. Mayerhofer and Pirquet: *Lehrbuch der Volksernährung nach dem Pirquetschen System.* Wien, Berlin, 1920.

ting height indicates normal nutrition and in allotting the Hoover feedings to the children of Austria only those below a certain Pelidisi have been provided with the American meals. The question as to the best standard for the estimation of malnutrition is still an open one but it will be important in the future to determine the relative value of the Pelidisi scale as compared with the height-weight-age ratio and other standards used in this country.

The nem differs from the calorie as ordinarily used in this country as a measure of the energy value of foods in two respects. In the first place, it is based not on an abstract physical unit but on an actual concrete food portion, one nem being equivalent to the nutritive energy of one gram of milk—(about two-thirds of a calorie). In the second place, the nem values of other foods are estimated not on the raw calorie basis, as has been the general practice in this country, but on the German plan, which takes account only of the calorie value which can actually be assimilated by the human organism. The use of nutritive instead of raw calories is certainly sound, although the difference between the two is not very marked and for purposes of popular exposition the conception of the nem seems much simpler than that of the calorie. In this country, however, popular education in the significance of the calorie has gone so far that it would hardly be desirable to attempt to introduce a new unit. The actual condition of feeding operations involving a million or more children on the Pelidisi and nem system is, however, a large scale experiment of the greatest interest to experts in nutrition and no one who follows Dr. Pirquet's computations can fail to be impressed with the tremendous advantage enjoyed by nations in which the metric system is in use.

### Importance of Cosmetics from the Viewpoint of Industrial Medicine

**S**UDDENLY her pocketbook was snatched from her hand! The hero pursued, overtook, recovered, and with a courtly bow returned it to its fair owner. She opened it and, before thanking him, powdered her nose!

This little drama of everyday metropolitan life may or may not be true, but it illustrates how firmly the cosmetic habit has fixed itself upon our American womanhood.

Time once was when a girl who heightened her beauty with a little rice powder was talked about; if she added a dash of rouge, she was a hussy; while a lip stick indicated strong criminal tendencies. Nowadays these things excite no more comment than the exposure of a pair of feminine

knees, and the modern woman paints, powders and does her eyebrows and hair in a way which would have seriously threatened her reputation in her grandmother's time.

It now appears that what has hitherto been regarded as a harmless form of exterior decoration is not without grave dangers and that there is a considerable element of grim truth in the old joke about the girl who painted herself so excessively that she had lead colic. The literature of lead poisoning contains a few scattered references to the occurrence of plumbism from the use of paint, rouge, and hair dyes, but until Barron and Habein, in a recent issue of the *American Journal of the Medical Sciences*, directed attention to the subject, Holland's article published in 1881 in the Third Annual Report of the Kentucky State Board of Health was the sole reference to the lead intoxications following the use of "Flake White" as a cosmetic. This extensively sold face powder is pure lead carbonate which has been ground to impalpability. It is cheap and as ordinarily applied has a lasting quality. It is dispensed as a lotion or as a powder. When used, the lotion is dabbed on and allowed to dry. If the powder is employed, it is first mixed into a thin paste by rubbing it between the palms with a little water. It is then applied to the face with some friction, particular attention being paid to the wrinkles. At first, it is greyish-white but on drying, a pearly white "complexion" results. Poisoning follows slowly and is often so mild in its manifestations as to escape detection, but frequently very serious intoxications and even death may follow. In five cases of poisoning due to the use of this cosmetic (Barron and Habein) four were fatal. It is entirely probable that mild lead poisoning from this source is very common and widespread, since this preparation may be purchased in almost any drug store. The obvious remedy is the enactment and enforcement of stringent laws prohibiting the incorporation of any toxic substance into any cosmetic and the examination of all face powders and beauty lotions now on the market and the immediate withdrawal from sale of any which contain poisonous materials.

From the viewpoint of industrial medicine the knowledge that plumbism may be produced by cosmetics is of tremendous importance, since it may furnish a clue to the origin of obscure cases of lead poisoning. It supplies a line of action to be used both in cure and prevention. Undoubtedly companies have sustained damage suits on this account where in reality the fault lay in the use of "Flake White" or some similar product.

In one of the cases reported by Barron and Habein there is a very significant observation.

Three years previous to the development of typical symptoms of lead poisoning, this patient's dentist observed a blue line on her gums. In spite of this unmistakable evidence of lead intoxication, her disease was allowed to progress until she weighed only seventy-two pounds and had developed bilateral wrist drop. In this woman's history there was a record of two surgical operations. Uncalled for surgical interference is frequently mentioned in the literature of lead poisoning.

---

### Eye Defects and Industrial Accidents

**T**HERE are 15,000 industrial blind in the United States, or 13.5 per cent of the total blind population, according to a report in a recent issue of *Science*, by Earle B. Fowler of the Committee on Elimination of Waste in Industry of the American Engineering Council. Eye injuries are factors in 10.6 per cent of all permanently disabling accidents.

Vision tests among employees reveal the wide prevalence of subnormal vision which necessitates excess eye fatigue and results in a reduction in quantity and quality production. Examination of ten thousand employees in factories and commercial houses found 53 per cent with uncorrected faulty vision.

The report suggests that visual acuity standards be determined for each grade of workers with the necessary minimum for each kind of work in order to avoid excluding workers shown by practical tests to be efficient producers. Bringing working conditions up to the best will improve the efficiency of workers with faulty vision, though correction of eye defects is indispensable to efficient production.

### The Complexity of Tropical Health Problems

**T**HE sanitarian of the temperate zone as a rule has a certain amount of technical knowledge of the public health problems of the tropics. He knows, for example, the various modes, mechanical and biological, of the transmission of the diseases of warm countries and he knows in a textbook fashion the measures to be taken for their control and eradication. To him, however, the entire equatorial belt is a hot region and he does not realize that the several nations of South America possess every climate known to man, parched deserts, low humid sea coasts, great temperate valleys, and high regions of frost and snow. Naturally, each of these presents an entirely different hygienic problem modified by the zoological environment, the food supply, and the nodes of human existence.

The public health worker visiting these countries finds himself handicapped by his ignorance of their geography and an inability to establish a sympathetic understanding with the people because of the differences in language. He is horrified at finding cities which were old before Manhattan was begun still without sewer systems. He sees milk of questionable purity marketed from a horse's back by an unwashed farmer, and the fly-infested markets appall him. In many cases he discovers that the drinking water is practically dilute sewage and if he does not tuck in his bed-net carefully, his nights are a period of exquisite torture and grave danger. The pot bellies of the naked children playing in the garbage strewn streets of bespattered mud and thatch villages tell him of the prevalence of uncinariasis and the paucity and unreliability of the vital statistics bring home to him the apparently absolute disregard for human life.

Plague is endemic in almost every country of South America and is gradually spreading from the ports to the inland towns remote from railways, there to cause acute perennially recurring epidemics. Smallpox is almost regarded as an inevitable and unavoidable incident of life. Typhus is rampant except in those situations where the climate does not permit lice to flourish. Dysentery, yaws, and pinta are almost everywhere. Yet these diseases which are hindering the development of one of the richest portions of the globe are apparently viewed with unruffled fatalism—an inarticulate helplessness.

The visiting sanitarian becomes critical and, unfortunately, he is apt to express himself freely regarding what he believes he has discovered, forgetting that the public health movement is a comparatively new thing in the world and that even the most enlightened nations have their areas of sanitary backwardness. He assumes that the conditions which he has observed exist because of sheer waywardness and carelessness, losing sight entirely of the enormous difficulties which face the men who are trying to do sanitary work in the tropics.

In practically every country of Central and South America there are one or more well trained men who are laboring in hygienic fields, frequently with only the half hearted backing of their respective governments, without a trained staff, without adequate laboratories, without modern hospitals, without sanatoriums, without sufficient appropriations. That these men succeed as well as they do is little short of marvelous. Yet they are doing things, really constructive things which are forming the basis of a sound national health. At Guayaquil, Ecuador, for example, yellow fever has been eradicated and the

Director General of Health, Dr. Wenceslao Pareja, is carrying on an active campaign against plague. In Venezuela, Dr. L. G. Chacin Itriago has built up a genuinely efficient National Department of Health, and has successfully combated plague in Caracas. Dr. Henry Hansen has stamped out yellow fever in northern Peru. Dr. D. M. Molloy has done the same in Nicaragua, and other workers of the Rockefeller Commission have done the same in Mexico.

To be sure, national sanitary development requires time, just as does any other form of national development; what has been accomplished by the Americans at Panama can be brought to pass elsewhere in the tropics and by other nations, but it must be remembered that the problem is much more complex and difficult in the tropics, where the parasitic flora and fauna are far more prolific than in the temperate zone.

### Dispensary Survey Develops Pay Clinic Idea

**A**N OUTCOME of the study of the dispensary situation in New York City made by the Public Health Committee of the New York Academy of Medicine and reported in earlier issues of *THE NATION'S HEALTH*, was the recent establishment of a pay clinic by the Cornell University College of Medicine. Expressions for and against this project have appeared in the public and medical press, voicing again the divided sentiments on the social responsibility for providing adequate medical, surgical, hospital, and nursing attention for all groups in the population.

The New York survey revealed a distressing situation wherein more than two million normally self-supporting persons, unable to afford the fees of specialists or diagnostic consultants were obliged to patronize the free dispensaries or go without attention. Ample facilities of every character are available to the rich and a well organized dispensary system attends to the needs of the very poor, but the large middle class—persons of limited resources and unwilling to accept charity—are apparently without satisfactory provision.

Pay clinics are to be found in a growing number of American cities, though frequently such clinics are specialized in character. Attending specialists as well as administrators testify to their worth and point out the urgent need which such clinics fill. Patients' fees have frequently made it possible to operate the clinics on a self-supporting basis and in some instances even increase the remuneration of the paid staff. Fees collected by the Public Health Institute of Chicago at its venereal disease clinics and those

charged by Cornell University are somewhat higher than in other clinics, but judging from attendance and the satisfaction expressed by the patients, the costs are within their resources. Reasonable fees are charged for the first examination, and medicines, laboratory and x-ray services are furnished at cost. The patient receives the attention of the necessary specialists and, in order to avoid hasty examination, a limited number of patients are cared for each day, thus assuring personal and unhurried attention.

Charges that pay clinics are unfair competition with the general practitioner are frequently heard. The trustees of the American Medical Association after considering the matter recommends that the fee charged by pay clinics be not less than that charged in general practice and that there be a cooperative relationship between the clinic and family physician whereby the latter can refer patients to the clinic and receive report of the findings.<sup>1 2 3</sup>

In addition to providing examinations by groups of physicians at a cost within the ability to pay of a major portion of the population and making the clinics practically self-supporting, the Cornell clinic is expected to provide a larger and richer supply of clinical material for teaching purposes, thereby advancing scientific investigations into the problem of disease.

### Public Health in the Special Session of Congress

**T**HE special session of the Sixty-Seventh Congress, which convened on April 11, 1921, and adjourned on November 23, 1921, had before it 143 bills concerned with some phase of public health. Of this number only six passed both houses of Congress and become laws. These laws include the Shepard-Towner act for the promotion of the welfare of maternity and infancy, the Willis-Campbell anti-beer legislation, a general deficiency bill in which provision is made for the continuance of the Interdepartmental Social Hygiene Board, the creation of a Veteran's Bureau, and two minor measures, one allowing the Cincinnati Post Office to use a special cancellation stamp for the Health Exposition held there in October, and a bill providing for the distribution of surplus army tobacco to ex-service patients in hospitals. During the approximately six months that the special session was at work, about 10,000 bills and resolutions were introduced in the House and about three thousand in the Senate. Only about 1 per cent of this number was concerned with public health.

## Insurance Data Seem to Promise a New Life Standard

HOW much extension in the length of human life should be expected in the years to come? In the fifty-five years between 1855 to 1910 the expectation of life was increased eleven years, according to life table compilations published by Louis I. Dublin in the *Statistical Bulletin* for December. Will it require a corresponding interval to bring about another increase of eleven years, or will life extension be more rapid, or less?

Doctor Stephen Smith, founder and first president of the American Public Health Association, and who was ninety-nine years old in February, voiced his belief in a new life standard of one hundred years in an address during the semi-centennial jubilee. "We have too long been content with the false code of the Mosaic law, that limits life to 'three score years and ten' with a possibility of reaching four score years. Biology teaches that the normal and potential life of man is one hundred years, that every child born is adapted in physical construction and function, to live a century."

It is obvious that a continued reduction in deaths from preventable causes and the postponement of deaths from other causes will markedly extend the life expectation of fifty-one and one-half years which existed in 1910. The effect on the longevity of human life by the elimination of certain causes of death is possible of definite measurement. Thus the loss from tuberculosis is equivalent to a reduction of three years in the life span of white persons; the loss from heart disease is one and three-fourths years, from cancer and Bright's disease one and one-fourth years each.

After considering the statistical evidence relating to the possibilities of life extension, Dublin ventures the statement "that the duration of human life may be extended considerably more than ten years and the expectation raised from fifty-one and one-half to sixty-five years by the application of conservation measures very well known to the medical and public health professions."

---

RECENT studies of the Department of Labor on the working conditions affecting the million and one-half children from ten to fifteen years of age who are employed in farm work in the United States decry the old conception of country life as idyllic and emphasize the fact that rural child labor is fully as flagrant an evil as was ever factory child labor. While it is not held in the report that all these children labor to their

own injury or in violation of existing child labor laws, fair play is nowhere accorded these youthful farm workers. The exploitation of children is not the vice of any single industry nor is it confined to any single section. In the tobacco fields of Connecticut Valley, the truck gardens of Ohio, the sugar-beet fields of Michigan and Colorado, the cotton belt, the Imperial Valley, long hours of labor, monotonous, back-breaking drudgery, and untoward living conditions characterize child labor. Child workers in Colorado showed 25 to 35 per cent retardation in school and over 70 per cent of a group of more than one thousand beet workers in Colorado exhibited postural defects. Absolute lack of educational opportunities was shown to exist in the children of seasonal workers in three hundred Baltimore families, and in Oklahoma children as young as five pick cotton regularly. There are no provisions in state or national laws to give protection or supervision to agricultural child laborers. Fourteen states specifically exempt agriculture from any restriction as to hours. Twenty-three other states do not mention it in the occupations for which hours are regulated and only eleven limit the hours.

If this great army of children is to be lifted above the dregs of the social stream which is carrying them on, it will be through educational influences during the impressionable and modifiable period of early youth. The real corrective for the rural child labor that is injurious to health and education lies in compulsory education. Something is being accomplished through the Farm Bureau through its County and Home Demonstration Agents, and new ways of child management have been introduced in some localities through the Boys' and Girls' Club, but if the situation is to be remedied, rural communities must assume a new attitude toward education and appreciate the biological and psychological necessity for the play activities of childhood.

---

THE first and second issues of *The Red Cross Courier* are before us, a weekly newspaper, which, while primarily for interdepartmental communication, is put up in true journalistic style and the story of achievement in all fields of Red Cross service is sufficiently interesting and important to bespeak an increasingly wide circle of readers. Its circulation should promote unity and enthusiasm in the ranks of Red Cross workers and lead to better mutual understanding among social agencies and a broader humanitarianism everywhere. If public sentiment has been slow to support public agents of health, news getting of this character and its wide dissemination should improve the situation.

## Health Problems Involved in Noise and Fatigue

Rhythms, Cadences, Periodicities Regulate Human  
Activities, but Noise Lessens the Aptitude for Work

By PROFESSOR HENRY J. SPOONER, M. I. MECH. E., F.G.S., ETC., MEMBER OF THE INTERNATIONAL COMMITTEE ON  
INDUSTRIAL FATIGUE, LONDON, ENGLAND

SOME twenty years ago an engineer, one who had been actively engaged for many years in the design of machinery, consented to write a book on "Machinery Design" for a famous firm of publishers. About eight years later the book was launched; and, strangely enough, it found a ready acceptance in the United States. This led to the author being invited to join some of the professional institutes of that progressive country, and also to his becoming acquainted with some of the leading engineers of the United States, notably Major Frank B. Gilbreth, America's most distinguished industrial engineer, with whom he has been in constant communication to this day. As is well known, Dr. Gilbreth was for years associated with Frederick Winslow Taylor, the father of scientific management, and since the death of the later has become the leading exponent of all that the improved methods of management stand for. But these improved methods which have worked such wonders in the way of increased output with less fatigue are based on the elimination or reduction of all forms of waste, particularly of human waste. Happily, this association with Gilbreth has kept me in touch with all the important develop-

*According to Dr. Henry Head pain is a necessary ingredient of every peripheral sensation, the comfort and the general effectiveness of the organism depends upon the capacity to dominate the external stimuli, physical exhaustion being the expression of the loss of that capacity.*

*The influence of noise, shock, and vibration—lacking periodicity—is wholly disorganizing and the correction of badly balanced machinery and of obviating in civil and industrial life the maddening, meaningless jangle of sounds that sap our nervous reserves becomes an urgent engineering problem, international in scope.*

ments in scientific management during the past decade, and has led me to study them, particularly that section which deals with the powers of human endurance, and of the effects of fatigue on human efficiency; a subject usually referred to as "Industrial Fatigue." These studies and researches stood me in good stead during the war, and I venture to believe enabled me to make my activities more useful to my fellow workers.

Now, apart from muscular fatigue, the output of the worker is primarily affected by the quality of the air he

works in, the efficiency of the lighting arrangements, and the amount of noise in his vicinity. But, strangely enough, although a great deal of attention has been paid to the heating and ventilation, and to the lighting of workshops and work rooms, and such like matters, very little has been done in any country to protect the workers against the fatiguing effects of noise. The fact is, most of us soon get used to noise of any kind, and we do not always feel the nerve strain due to it, nor are we often aware of its fatiguing effects; as the ear soon gets accustomed to noises that at first were most disturbing. For instance, a person takes up his abode near a railway line, and the first night or two cannot sleep owing to the disturbing effects of the passing trains or of shunting operations; or he may be at the seaside near enough to hear the roll of the waves, but soon these noises cease to interfere with his sleep; in other words, there is apparently an *aural tolerance*, peculiar to each individual, which gradually functions. Thus, having grown so accustomed to hear noise at every turn, wherever we may be, the tyranny of almost unbearable noise in many of our industrial activities, in our streets, and sometimes in our homes, is apt to be accepted as something in the nature of things that must be endured, and to no small extent the normal being becomes practically unconscious of its injurious effects upon his nervous system. But there can be

\*Chadwick Public Lecture delivered at the Public Hall, Blackburn, Lancashire, England, November 21, 1921. Published through the courtesy of the International Committee on Industrial Fatigue. Read before the Committee on the Elimination of Fatigue, New York City, December 5, 1921.

no question that those who are neuropathic, or have a highly strung nervous system, suffer tortures through noises that apparently do not much distress those of a phlegmatic temperament. The case of the former is aptly set forth in the satirical *Obliviad*, as follows:

Chromatic torture, that some saw-mill near,  
To drown these notes, or, could I  
Codrus hear!  
Not touch of file, but grating sound  
of rasp,  
And pen to splinters shiver'd in his  
grasp,  
Such forced, alas! on the long dreaded  
doom,  
Much discord drive another to the  
tomb;  
No kind mechanic to attend my call,  
And give a double sash, or thicker  
wall;  
Torn every nerve, intolerable grief,  
And the Vice-Chancellor refuse relief!

Strangely enough, it sometimes happens that noise in an industrial works is a greater nuisance to those residing near the works than to those working within them. Some three or four years ago I was professionally engaged in such a case, where, under duress, the proprietors of the works called me in to deal with the problem of abating the nuisance, and this led me to undertake a certain amount of research and experimental work in this field, and to give a great deal of attention to the general problem of noise prevention and reduction. So, when in the early part of this year I was invited—as a member of the International Committee on Industrial Fatigue—to read a paper before the American Society of Industrial Engineers at their National Convention held at Milwaukee in April, I selected as my subject “Fatigue Due to Noise, and Methods of Elimination,” and I believe that this paper represented the first formal attempt that had been made to call attention of engineers and others to the importance of the subject. This humble effort on my part met with such a flattering reception that I am venturing, in the Chadwick Public Lecture, my second communication on the subject.

It will be convenient to commence with a few definitions and maxims relating to fatigue, and a definition of noise, and then to proceed with a brief description of the ear, and to touch on matters relating to hearing and deafness, then to deal with the effects of noise, and such like matters, and to attempt to classify the primary kinds of noise that should receive attention; and finally to suggest how some of the problems that arise in noise prevention and reduc-

tion may be tackled.

### Fatigue and the Ear

The ear is a very complex and highly developed organ. Through it the nervous system is easily affected and fatigued.

A period spent in the midst of working machines and mechanical operations, causing deafening and strident sounds of a very wide range, and shocks to the auditory nerves, produces a feeling of sensory fatigue. Although this fatigue attacks primarily a single organ, it little by little extends to the whole of the nervous system, leading in some cases to such a feeling of weariness that it may impair the capacity for work in a greater degree than severe muscular fatigue. Nothing is more fatiguing to some workers than a noisy, unrestful, fussy atmosphere.

There is far too much avoidable noise in many industrial works. Worry is insidious and it spreads over the brain like a leaven. The constant dwelling upon an idea which becomes an obsession tends to destroy the mental balance. Nerve and tone largely depend upon the mental attitude. Whatever causes mental depression or discord exhausts the force in the cells of the brain, and tends to lower the nervous system generally.

The same cause may give rise to pain or pleasure according to the individual temperament. As long as we are in good health we are little aware of intellectual fatigue, but as soon as ill health comes upon us we find how exhausting brain work is. Extreme fatigue, whether muscular or intellectual, produces a change in our temper, causing it to become more irritable.

Attention is a limited quantity; it requires time. If, then, attention be distributed over too wide a field, there is a corresponding loss of intensity and of distinctness.

We could lengthen our lives if we took needed rest habitually, for it is habit that kills or cures.

The problem of scientific industrial management, dealing, as it must, with the human machine, is fundamentally a problem in industrial fatigue.

There are considerations so inapplicable at present in terms of physiology as to be called “psychological.”

### Definition of Noise

Johnson's dictionary definition of noise is: “Any kind of sound, generally applied to that made by brutes, or inanimate bodies, and implying excessive loudness; an outcry, clamor, or boasting and impertinent talk.”

Of course, we all realize that the sensation which we call noise is quite different in character from the musical sensation of sound. Noise is produced by irregular, unperiodical movements of those bodies which convey sound. From daily experience we learn to distinguish one noise from another. We therefore call them grating, rasping, creaking, hissing, and banging noises. Their character depends partly upon the strength of the separate shocks, partly upon the rapidity with which they follow each other, but partly also upon the presence of real tones of various pitch which are intermingled with the noise. Low tones are often connected with a grating noise, and with a hissing noise generally very high tones, which impart to them their peculiar character. It is often by this intermixture of tones that we are able to determine the cause of the noise.

### Hearing and Deafness

Without attempting minutely to describe the ear, which has been called the second gateway of wisdom and is regarded as the most complex of all parts of the human frame, I may explain that the external ear serves in some measure for collecting the undulations of sound transmitted through the air, and reflecting them into the auditory passage, at the bottom of which they strike against the membrane of the tympanum or drum, which, being larger and more movable than some of the subsequent parts, is capable of transmitting a stronger impulse than they would immediately receive. The impulse received by the membrane of the tympanum is conveyed by a beautiful mechanism to the cochlea, a detached channel, which acts as a micrometer of sound. The inner membrane of the cochlea is lined—as Corti has shown—with about three thousand minute fibers, membrane of the tympanum or drum, all connected with the acoustic nerve; each of these is tuned for a particular note as if it were a delicate resonator, and only vibrates in unison with this note, being deaf for all others. Hence, however complete external sounds may be, the microscopic fibers can analyze and reveal the constituents of which the sounds are formed. The tympanic cavity passes downwards, forwards, and inwards into the eustachian tube. This canal, which connects the middle ear to the back of the throat, has two orifices which open, one into the pharynx and one into the drum. It is said that this canal permits us to hear our own voice; it also allows

the pressure on both sides of the drum to equalize when the mouth is opened. This is why artillerymen instinctively open their mouths at each shot of the cannon.

The faculty which some individuals possess of emitting tobacco smoke by the ear depends upon a perforation of the drum-head.

Strangely enough, many parts of the ear may apparently be spared without very great inconvenience; this is due to the fact that we hear very perfectly by means of impressions communicated by the sonorous waves to the auditory nerve by the bones of the skull and of the face, or by the *natural* teeth, and through them to the large bones of the head; and even when the membrane of the tympanum and all the small bones have been destroyed by disease, the undulations of the air still continue to affect the organ. Hence it is that, even when the ear is stopped up, the ticking of a watch, if placed between the teeth, can be distinctly heard. A case is quoted of a man who had the auditory canal quite obliterated, and yet could hear sufficiently to carry on his business; however, on covering his head with a skull cap, he became deaf immediately. But a witness in a law case recently said he could only hear when his hat was on—it was probably a hard felt one.

A merchant at Cleves who had nearly lost the ability to hear, was sitting near a harpischord while someone was playing, and found that as his pipe rested on the body of the instrument he could distinctly hear all its notes.

The instrument called *audiphone* or *dentiphone* is constructed on this principle, and consists of a fan-shape vulcanite plate—held between the teeth—whose vibrations are conveyed to the aural nerve.

It appears that about 40 per cent of deaf cases are not congenital, but acquired through accident or disease. Among the causes of acquired deafness are fright, falls, injuries, cold and exposure, and smallpox, fevers, etc. A good friend of mine, a distinguished peer and a great industrialist, recently wrote to me as follows:

I am convinced of this, that in later years, since I lost my hearing, I have been able to concentrate my thinking much more effectively, and have been able to do a larger amount of work without being conscious of any resulting increased fatigue. This may be merely constitutional, or it may be that the exclusion of sound has a bearing upon the position.

The modern conversation tubes and

double auricles are marked improvements upon the old ear-trumpets, but from my investigations and experiments, I have formed the opinion that a more efficient instrument could be devised.

It appears that people with the largest ears hear farthest, and distinguish sounds with most facility, and it has been suggested that this consideration has induced some savages to adopt the strange custom of extending the lobe by piercing them to hang in them rings, etc. It is a well known fact that the hearing of blind people becomes extraordinarily acute. Darwin said: "The late Justice Fielding—who was blind—walked into my room, for the first time, when once he visited me, and after speaking a few words said: 'This room is about 22 feet long, 18 feet wide and 12 feet high,' all of which he guessed with the greatest accuracy with the ear."

Strangely enough, there is a remarkable falling off in the power of hearing high notes as age advances.

#### Recurrent Sounds

Men working together or in gangs instinctively tend to work rhythmically: thus, two carpenters planing the same piece of wood will move their planes alternately so that, when one is pushing his forward, the other is drawing his back; thereby securing a recurrence of sounds, which from their inequality would be harsh if they were heard simultaneously. In the same way two paviors, driving in stones, bring down their hammers time about, to the accompaniment of peculiar sighs or grunts, and so do men at the smithy when they are forging a bar, and the smith, when he has dealt a succession of monotonous blows, relieves his ear by letting his hammer ring musically on the anvil; and I need not tell you how sailors, heaving the anchor or hoisting the sail, sing together in chorus; or remind you that the most serious of hard work, fighting, is helped and inspired by the drum, the bagpipes, and the trumpet. As to the paviors, the sighing noise they make fails to ease their labor and is positively harmful. Sir Benjamin Richardson who had medically attended many of them, explained that "as they let down upon the laid stone the heavy hammer, they force out of their chests a large volume of air. They produce by this movement a curious noise like a long sigh, and they think that by this means they in some manner relieve themselves of strain of labor. This idea is purely imaginary, and the

injury inflicted by the practice it engenders is of a serious kind. It brings on dryness of the throat and hoarseness, a sense of exhaustion in the muscles of the chest and a feeling of emptiness within the chest."

#### Effects of Noise

Medical authorities are agreed that noise is injurious to health, and that violent or loud sounds are unfavorable to the brain, and are an undoubted source of fatigue and nerve strain. As Dr. H. M. Vernon tells us, "the fatiguing effect of noise is chiefly due to its influence on the faculty of attention. Noise distracts attention and therefore necessitates a more intense mental application to the task in hand in order to overcome the distraction." Indeed, very few people are capable of concentrating their minds on any subject in a noisy atmosphere and in exceptional cases, where mental work is done by a worker who is apparently unaffected by even violent noises, there can be little doubt that sooner or later he will have to pay the penalty. As to noise in textile factories, I may quote my friend, Dr. Stanley Kent—who said at the Efficiency Exhibition, "the deafening noise in the mills of the North will have to be reduced, as the workers are becoming conscious of its fatiguing effect." "The work of weaving is exacting, as it is very noisy and it requires constant attention," writes Dr. Vernon. It is well known that trunk makers, riveters and boiler makers, etc., usually become deaf. Hence the saying, "deaf as a trunk maker." Sir Benjamin Richardson, in writing about boiler makers, said, "they are deafened, in some instances markedly, from the constant din, and in rare cases the circulation through the brain is affected, so that giddiness and nausea follow as results. These phenomena are most observed in the early career of the worker; they are diminished when the sensibility of the ear to the persistent sound is decreased." Sir Benjamin, in referring to the somewhat short lives of commercial travelers, said, "the shrill whistle of the engine in the stations, with the constant bustle and worry and excitement, all add also to their share of the mischief."

The deafness of army gunners and bell-ringers is proverbial, often due to perforation of the drum of the ear, when the membrane has been too sharply impressed with the violent vibration of air due to noise.

"All the world is sensible of the uncomfortable effect that certain

sounds have upon the nerves, and consequently upon the spirits; and if a sinful world had been filled with such as would have curdled the blood, and make the sense of hearing a perpetual inconvenience, I do not know that we should have had a right to complain," wrote Cowper in one of his letters. "I am constitutionally susceptible of noises," wrote Lamb. "A carpenter's hammer in a warm summer noon, will put me into more than midsummer madness. But those unconnected, inset sounds are nothing to the measured malice of music." The fact is that most middle aged persons living and working in big cities are slightly deaf, the roar and rattle of the traffic, motor-busses, taxis, traction engines, sirens, and the nerve-racking telephone and irritating clatter of typewriters being responsible. "That night was my idea of hell," says Mrs. Asquith, describing the noises of the preparations for a sea voyage. "Next morning, the sea was still, but the screw below made me feel as if I had no inside worth mentioning." We all know how injurious to our nerves the crowing of cocks, the barking and howling of dogs, and the cater-wauling of cats, can be; also the efforts of musical people. "Lucy has taken up the piano again"—quoting from a letter which was read in a recent law case. "She plays six bars over and over again. It is just like brain fever." . . . "Flow of talk, it flowed like a turbid torrent." Even in public dining places we cannot escape from noise,—which fact led a sufferer to remark, that "what is badly wanted is an inventor who will find some way of taking the din out of dinner and putting the rest into restaurant."

But the abnormal, is often very abnormal. Recently, a foreign looking passenger in the London tube, made himself noticeable. Waves of ecstasy passed periodically over his face, and he wrote hasty signs on the backs of envelopes. "Magnificent!" he remarked to a fellow passenger as they ascended in the lift. "What music in the creaking of the wheels, the grinding of the brakes, and the crash of points. I have an inspiration for a whole symphony! I wonder the idea never occurred to Stavinsky."

### Sleep and Rest

Noise, of course, is the greatest enemy of sleep—life's restorative and most efficient comforter, and, as Dr. Forbes Winslow tells us, "if the recuperation does not equal the expenditure, the brain withers. The time of disturbance from necessary sleep is

infallibly destructive to mind, body, and estate." In her standard work, "The Psychology of Management," Dr. Lillian Gilbreth also aptly states the case for adequate sleep and rest as follows: "All unnecessary noise should be eliminated, and provision should be made, where possible, that the workers may enjoy their sleep or rest hours in perfect quiet; . . . even though they are not disturbed enough to be waked up, every noise that is registered in the brain affects the body; for it is now conceded that the body reflects every phase of mental activity."

"So far as an overpowering heaviness, a prostration of strength, and an utter inability to control our thoughts or power of motion, can be called sleep, this is it; and yet we have a consciousness of all that is going on about us, and even if we dream words which are really spoken, or sounds which really exist at the moment accommodate themselves with surprising readiness to our vision, until reality and imagination become so strangely blended that it is afterwards almost a matter of impossibility to separate the two." So wrote Charles Dickens.

We have all suffered agonies from the garrulous who talk in loud voices and gabble continuously, unmindful that much talk and much noise injures the ears and deranges the nerves. "Doctor," said such an one, "I want you to prescribe for me." "There is nothing the matter, madam," said the Doctor, after feeling her pulse; "you only need rest." "Now, Doctor, just look at my tongue," she persisted, "what does that need?" "That needs rest, too," replied the Doctor.

### Use of Sound Deadeners

We have seen how noise is a cause of deafness, and that persons so affected can get some relief, and increase in their power of hearing by using such instruments as the audiophone. But prevention is better than cure, and a suitable form of ear-stopper may be used with advantage to deaden noises when they interfere with the workings of the mind. Herbert Spencer, the great philosopher, found much relief by using a pair of home-made ear-stoppers. They took the form of a spring band, almost semicircular in shape, with a little velvet-covered knob at each end, these knobs being pressed by the band onto the flaps of the ears. Returning from the Atheneum each evening about nine, he would sit with the home circle, and, if the conversation proved

too trying for him, he would produce his ear-stoppers and shut himself off from the world of sound.

Noise of any kind was apt to make him very angry, and he used the word "pestilent" indifferently to men, tunes, or sparrow—when the chirping of the latter disturbed his slumbers. But many other expedients have been devised to protect the inner ear, the ear drums, and the aural nerves against mechanical injury, air shocks, and irritating noises without impairing the hearing. These devices have been named antiphones, ear defenders, sound deadeners, ear protectors, etc. They are intended for use to protect the ear against shock, particularly in gunnery practice; but in all cases where there are noises of great intensity, high pitch, or excessive persistence, the ear should be protected; as it is, these noises lead to injuries of the tympanum or drum, and the nervous apparatus of the ear, such injuries in turn often reacting upon the entire nervous system. Some of the best known ear protectors I will proceed to describe.

The *Antiphones* are the simplest sound deadeners, and they have been extensively used in the Army and Navy to protect the ear against the effect of gun-fire, etc. They consist of plastic balls composed of wax and wool, and are moulded into the external ear by the finger.

The *Aurotector* consists of a pair of plugs, made (in three different sizes) of an elastic composition, and they are placed in the holes of the ears when used. These are also very simple, inexpensive devices.

The *Dull-a-phone* consists of a pair of elastic balls mounted on screws, which are screwed into plates shaped to fit the chamber of the outer ear, and are adjustable. They are a German invention, but are little used in this country.

The *Mallock-Armstrong* Ear Defenders consist of hollow, funnel-like pieces of vulcanite with ball-like ends to fit the hole in the ear, the other and larger end being fitted with a gold wire screen. They are made in several sizes; and, as air can pass through them, no trouble can occur due to air being pressed into the ear when they are fixed in position.

### The Basic Facts of Noise

In giving consideration to the problems of noise we should be acquainted with the following truths relating to sound and its propagation:

(1) Sound always originates in some movement of a body from which it is emitted, and becomes audible

only when any medium exists that will convey the vibrating motion of the sounding body to the ear.

(2) Sounds differ in the properties of quality or tone, pitch, distinctness, intensity, loudness, and volume; they also vary in their nature, according as they take the form of noise, music, or articulate speech.

(3) When rapid successive impressions on the ear follow at regular intervals, a continuous sound is heard, the pitch of which depends upon the frequency of the repetitions; such notes are, in all but the most exceptional cases, caused by vibrations of some elastic body.

(4) Sound is conveyed most frequently through the atmosphere, but nearly all bodies will transmit it.

(5) Sounds traverse the air at a uniform velocity, but with a constantly diminishing strength; they naturally follow a straight course, but their direction is liable to be modified by the objects they meet. They may be reflected, deflected, conducted, or absorbed. All sounds move with the same velocity; the gentlest whisper moves over the distance to which it extends as rapidly as the report of a cannon the same distance.

(6) There is a great similarity between the laws that govern the propagation of sound and of light.

(7) Such bodies as produce a continuous sound, like a bell, are termed sonorous. The sonorous quality of any substance is connected with its hardness and elasticity. Thus lead, rubber, and such like substances, are non-sonorous.

(8) Bodies capable of vibrating so as to produce a sustained sound are ordinarily apt to vibrate spontaneously when a sound of the same pitch is excited near them.

(9) Whatever diminishes the elasticity of the air impairs its capacity of conducting sound. Thus moisture, fogs, snow, and rain obstruct the passage of sound. Hence traffic in a fog may be only a few yards away and not heard.

(10) The velocity of sound through air is 1,142 feet per second, equal to thirteen miles per minute, or one mile in four and a half seconds. Hence the pulse of the wrist of a healthy man—which beats nearly once a second—indicates a distance of nearly a quarter of a mile per beat.

(11) The velocity of sound through solids is very much greater than through air. Thus the velocity through fir wood is 17,400 feet (equal to three miles) per second. The scratch of a pin at one end of a piece

of timber fifty feet long may be heard distinctly by an ear placed closely to the other end, but could not be heard through the air twelve feet.

(12) The ordinary range of sounds audible to the human ear was stated by Euler to extend from a range of thirty vibrations to 7,552 per second. But Mons. Savart at a later period found it possible to produce audible notes having as few as fourteen or fifteen single vibrations in a second, and up to as many as 48,000.

(13) The intensity of sound varies with the density of the air. Thus it is said that at the top of Mount Blanc, or in a balloon at about that height, the human voice is much weakened, and that the report of a pistol resembles the noise of a boy's popgun, while in a vacuum there is no medium for the transmission of sound—as is proved by the experiment of the bell in the receiver of an air-pump. On the other hand, the compressed air in a diving bell causes even a whisper to be painfully loud.

(14) The intensity of a sound decreases as the square of the distance.

#### Primary Noises Classified

The general problem of noise is not a simple one. However, the following is an attempt to classify the primary kinds of noise that demand attention:

##### 1. *Road and rail traffic.*

(a) Noise due to the condition of the roads.

(b) Noise due to the working and running of the vehicles on our roads, railroads and in the tubes.

(c) Noise due to the shrieking of

railway whistles, and to shunting operations, etc.

##### 2. *Industrial operations in which machinery is used.*

(a) Noise due to the running of prime movers.

(b) Noise due to transmission machinery.

(c) Noise due to the working of machines.

##### 3. *Industrial operations in which machinery is not used.*

(a) Noise due to the use of hammers, and other impact tools.

(b) Noise due to the handling and movement of materials and work, etc.

##### 4. *Streets and the home.*

(a) Noise due to cab whistles and street calls.

(b) Noise due to music, etc., in adjacent houses and flats.

(c) Noise due to church bells, and to crowing cocks, etc.

The author is not aware of any case in any country in which the engineer has been called upon to design and construct machinery, vehicles and roads, etc., from the standpoint of noise—with the exception perhaps of the machinery for automobiles—but he knows of cases where the noise from factories has been so intolerable to people living nearby that they have applied to the High Court for an injunction, and an engineer has been called in to deal with the nuisance, and has succeeded in greatly reducing noises which to business people and others occupying premises adjacent to the works, reached a degree almost beyond human endurance.

(To be continued)

## ASSOCIATION LETTER

By WILLIAM ALFRED SAWYER, SECRETARY

SOME time ago each member of the Association was sent a statement of a special assessment. Some of the members have taken this statement seriously and responded by sending in not only one new member, but several; others have apparently ignored it. It was ever thus with important matters—the few carry the load for the many,—but the interest of the Association demands that each and every member would seriously undertake what he can do to assist in this membership campaign.

One member is not a very heavy assessment. Will you not get busy

and try once more to think of someone who should be one of us?

In reading over the Constitution and By-laws, I find that provision is made for associate members as well as active members. Only physicians who are actively engaged in the practice of industrial medicine or surgery, or who are engaged in the investigation of industrial problems shall be eligible for *active* membership. Other *physicians* shall be eligible for *associate* membership. Associate members have all the privileges of active members except the privilege of holding office and voting

for officers and directors, and for amendments to the Constitution and By-laws.

Please note that associate members must be physicians. Doubtless there are a few in your community who would like to be members of our Association. Will you do what you can to secure someone?

The membership campaign is in full swing.

For (\$2.00) two dollars a new member's dues will be paid to May 1, 1922, the end of our fiscal year, or for (\$6.00) six dollars, dues will be paid to May 1, 1923. This is a saving of one dollar. Membership in the American Association of Industrial Physicians and Surgeons gives:

(1) Our official journal, THE NATION'S HEALTH, which contains full reports of all the affairs of the Association, together with other interesting articles on industrial medicine.

(2) Bi-monthly abstracts of current industrial medical literature.

(3) Reports and digests of interest to those engaged in industrial work.

This is an every member campaign. Nothing can be accomplished without your help. We cannot reach the mark necessary unless you do your share.

#### TO OUR PRESENT MEMBERS

*Our Constitution provides for active, associate and honorary members.*

*(a) Active membership is for physicians holding either full or part-time industrial positions, or those engaged in the investigation of industrial problems.*

*(b) Associate membership is for physicians interested in any phase of industrial medicine. Associate and honorary members are not permitted to vote or hold office. The dues are the same for each.*

How many members have you secured? Some have sent in several, others none.

The latter part of January another abstract of industrial medical literature was sent to the membership. If you did not receive yours, please notify the Secretary. With this abstract was a letter regarding the membership campaign, again reminding you that the harvest time for

members is at hand, and the Association needs the cooperation of everyone. There has been a generous response thus far, but we need your continued effort. Have you done your part?

If the Association is worth anything to you, it will doubtless be worth something to another. It is surprising how many desire membership in the Association as soon as they hear of it. As there are doubtless hundreds scattered here and there who know nothing of the Association, a word from you may add another member to our ranks.

Don't forget your assessment of one new member. **DO IT NOW.** If each member gets an additional member, victory is ours. And don't overlook the fact that you may know of some physicians who would be interested in an associate membership.

The Secretary is exerting himself to the utmost to make this campaign a success, and is willing to work still harder. Applications are not exactly pouring in as yet, but they are coming slowly and surely.

Please "step on the gas" and get that one new member and **DO IT NOW.**

## Labor Camp Sanitation in California\*

### A Program Instituted for the Correction of Slovenly Housekeeping in Camps

By R. JUSTIN MILLER, ATTORNEY AND EXECUTIVE OFFICER OF THE COMMISSION OF IMMIGRATION AND HOUSING OF CALIFORNIA, SAN FRANCISCO, CAL.

THE Camp Act in California requires that every sleeping place in such camps "shall contain sufficient air space to insure an adequate supply of fresh air for each person" occupying such place. The Commission has interpreted this provision to require an air space of from four hundred to five hundred cubic feet, according to other conditions existing in the camp. Of course in the old days of camps roofed by the open skies there was no problem of air space and ventilation. Even then, however, rigorous climatic conditions made the open air camp impossible in a good many places, and consequently the "old days" also frequently saw dilapidated tents and old barns, stables and henhouses crowded with men, women, and children, to whom

fresh air as well as the common decency which goes with reasonable privacy was denied.

Sometimes even today the Commission's camp inspectors run across ex-

treme conditions of this kind. During the last Spring, while the asparagus harvest was at its height in the delta lands of the Sacramento and San Joaquin Rivers, one of the in-

In the old days camps roofed by the open skies at least offered no objectionable stuffiness.

\*Part I of this report was published in the November, 1921, issue of THE NATION'S HEALTH.

The platform bed at its best, built continuously around the bunkhouse. In its worst forms the separating boards were eliminated by degrees and long before the end of the season they were filthy and vermin-infested.

spectors found an old dwelling of ten rooms which had been converted into a bunkhouse by a Hindu operator, and which was being occupied by seventy-seven people—men, women, and children. There were eighteen men, fourteen women, and forty-five children living in this building. In Madera County in the San Joaquin Valley an Armenian Camp Operator was convicted and imprisoned for housing fourteen people, men, women, and children, in one room fourteen by sixteen feet in area.

It should be stated in this connection that even where plenty of bunkhouse space is provided, sometimes the workers prefer to crowd into some of the houses and leave others vacant. There is a lesson here to be learned by both the camp operator and the camp employee, and this disregard of sanitation, born of ignorance, which is to be found on the part of many workers, provides a basis upon which some of the less progressive operators attempt to avoid compliance with the law.

### Bunks and Beds

The law requires that "suitable bunks or beds shall be provided for all employees. Such bunks or beds shall be steel, canvas or other sanitary material, and shall be so constructed as to afford reasonable comfort to the person occupying same." These accommodations must be furnished free of charge. The camp operators very generally prefer metal beds because of the tendency of some of the workers to break up wooden beds or cots and to steal canvas beds to use as a covering for their "bundles."

One of the worst evils of the old time bunkhouse, was the "platform" bed, characteristic of the "flop-house" type of camp. The platform bed consisted of a continuous platform built,

frequently, all the way around the bunkhouse, sometimes without even board partitions and filled with straw. In some cases there was not even a platform; the straw being piled on the ground and held in place by a twelve-inch board at the foot of the bed. The illustration given of this type of bed shows it at its best. It was too often marked by the elimination by degrees of even the foot board. These beds quickly became infested with vermin; it was impossible to keep them clean and, long before the end of a season, they were in a filthy condition. The men who occupied them were either long-suffering or lacking in the first principles of self-respect and they usually added to the filth by contributions of papers, old clothing, shoes, tobacco containers and other wreckage.

Another bad feature of these bunkhouses was what is called the double-deck bed and the triple-deck bed. One such bunkhouse inspected had thirteen occupants, each having approximately one hundred forty cubic feet of air space instead of the required five hundred.

The days of double-deck beds and

crowded quarters are about gone and it is a pleasure to note the conditions which prevail generally today. In place of the ramshackle old barn and the dilapidated tent, we now find bunkhouses of a better type, with single-deck beds properly spaced at least twenty inches apart. Of course many of the larger camps maintain bunkhouses with standard beds and equipment of the type familiar to everyone, but even the poorer more isolated outfits are complying with the law and providing sanitary facilities.

The law does not require that mattresses or other bedding be furnished free of charge, but if the worker requests such accommodations then the operator is required to furnish them and is allowed to make a reasonable charge therefor, deducting the amount from wages if necessary. This last provision has only recently been added to the law, but even prior to that time many operators voluntarily furnished such accommodations. This is only one of many evidences of the fine spirit which has been shown by the higher class operators throughout the state.

### Food—Cooking and Serving

One of the most important features of the labor camps is the equipment provided for the storing, preparing and serving of food; the "cookhouse" or the "cooktent," as it is generally known among the workers. The kind of food used and the way in which it is served may be sufficient in itself to determine whether there will be a contented efficient crew or a grumbling inefficient one. In the temporary camps, where equipment is reduced to a minimum and in isolated places where food must be brought from a long distance the problem becomes very difficult. Two of the most vivid and pungent memories of the

The double-deck bed and even beds triple-deck were features in some bunkhouses, always connected with over-crowding and deficient ventilation.

cookhouse of ten years ago are the odor of bad meat, and the odor of flies. Some people perhaps do not know that there is any odor about flies, but the nauseating stench which accompanies them where they exist in large numbers will never be forgotten by one who has lived and eaten among them. The loose-boarded, unbattened and unscreened cookhouse and the open cooktent were of course ideal locations for spoiled food and fly-breeding. The already low "morale" of the camp cook did not usually long survive the first warm days; he soon began to contribute to the general disorder and filth. It is very probable that many an office camp operator who prided himself on the high quality of food which he sent out to his camps was painfully surprised when he chanced to see the condition in which it was served. The photographs are shown of the cook's own domain in the rear of a highway construction cooktent, and of the old "cook-wagon" which was a familiar sight of the old days, especially in connection with haybaling and threshing crews. This wagon usually constituted not only the cookhouse, but the residence of the cook and his family as well. The paraphernalia hanging on and scattered around the wagon indicates that it was well equipped for light housekeeping, even though it may not have been just the best outfit for the storage and preparation of food for a crew of men.

In the vineyards and fruit camps where only temporary protection from the sun was attempted it was very usual to find camps in which large numbers of families are employed and in which men, women, and children of all nationalities and ages are thrown together. If proper facili-

ties are not provided, the bad results are immediate and obvious.

The last legislature has added a provision to this section of the law which will do much to correct slovenly housekeeping in the camps, and will also eliminate the cracked, chipped, bent and broken crockery and cutlery which tends to accumulate. The best feature of this and other requirements designed to improve dining facilities is that it is resulting in an increasingly higher standard of living among the men themselves, and the "rough-neck" who used to shovel the scraps from his plate between his knees onto the floor is now very quickly disciplined by the cook or by the other men.

### Bathing Facilities

Under date of June 19th, 1920, a letter was received from a camp operator in one of the northern coast counties of the state which reads in part as follows:

I received your notice in due time and would like to ask a few questions in regard to the requirements. I don't know how I could install a shower bath in my camp ground. I have three good hand pumps for drinking water. The Indians wouldn't use a shower bath if they had a dozen. I am on the banks of a good running stream and they could take a bath as many times as they want to. . . . their aint one family in ten thousand that has a shower. I never had one in my life and *I am just as strong as you are.* . . .

The Commission's answer on this point went back by return mail as follows:

. . . The law requires that adequate bathing facilities must be provided at every labor camp. A running stream of water does not constitute adequate bathing facilities for several reasons. In the first place, the cold water of a running stream is not particularly conducive to cleanli-

The cook's own domain in the rear of a highway construction cook tent.

ness nor is it particularly convenient for taking a bath. In the second place there is hardly that degree of privacy attached to bathing oneself in a running stream which runs right beside the camp which the law would interpret as constituting either adequacy or comfort.

Your statement, "The Indians wouldn't use a shower bath if they had a dozen," sounds so remarkably like the same statement which has been applied to practically every other type of laboring man in California several hundred times that we are beginning to wonder just how the labor camp operators of California have become so thoroughly advised on the manners and customs of these people. Our wonder continues to grow when in every case that showers are installed, the laborers begin to take their baths, and we have many letters on file in our camp department records wherein employers who at first believed just as you do, have voluntarily admitted that they didn't know what they were talking about, and that the laborers would stand in line waiting their turn to take a bath.

The only other alternative to shower baths which would satisfy the law are tub baths. Tub baths are much less sanitary than are showers and it is true that laboring men generally will not use tubs as freely as they will showers. For this reason, and for the further reason that it is much cheaper to install and to maintain showers, our inspectors have been instructed to recommend the installation of shower baths. The "shower head" is an inexpensive affair and as a temporary measure you can make one by punching holes in the bottom of an oil can until the shower head which you order shall have arrived at your place. Then you can put a barrel upon three poles, fill it with warm water and you have a complete outfit. Of course it would be far simpler for you to attach a hose to the shower head and to run water through it. The methods that I am suggesting are merely tem-

The double and triple bed has been superseded in most of the better camps by beds placed as shown in this lay-out, where the beds are at least twenty inches apart, the rooms clean and airy.

This cook wagon is typical of the old days. The paraphernalia about the place shows that it is better equipped for light housekeeping on the part of the cook and his family than for the storage and handling of food.

porary ones and indicate the ease and lack of expense which are attendant upon the installation of facilities of this character. If you cannot find a plumber in Ukiah who can install a shower for you, our inspector will be glad to give you full information about the subject when he next comes to see you. It will be necessary, however, for you to comply with the law in this respect.

This illustration is typical of many and tells in part the story of bathing facilities in the labor camps. Of course some operators did not even provide "good running streams" and some have been forced to use tubs because of lack of sufficient water for showers. In the main, however, the shower-bath is a permanent and popular institution.

Section four of the California Camp Sanitation Act reads in part as follows:

For every such camp there shall be provided convenient and suitable privy or other toilet facilities, which shall be kept in a clean and sanitary state. A privy other than a water-closet shall consist of a pit at least two feet deep, with suitable shelter over same, and the openings of the shelter and pit shall be enclosed by screening or other suitable fly netting. No privy pit shall be filled with excreta to nearer than one foot from the surface of the ground and the excreta in the pit shall be covered with earth, ashes, lime or other similar substance.

To tell the story of the toilet facilities provided in the days before the Act went into effect would be merely to compile details of filth and insanitation. In those days the presence of a crew in any neighborhood meant that before long every fence corner, creek bottom, excavation, tunnel, rear of barns or other buildings would become shambles and breeding places for flies and disease. Sometimes a burlap shack was erected and a scantling nailed across two uprights. This was even safer in those days than

wooden buildings equipped with cross boards and individual holes because the latter type of toilet merely served as a more aggravated collector of excreta and filth. There are instances on record where these toilets were also used as garbage containers and were sometimes filled with entrails of animals butchered in camp. The very fact that the burlap shack was temporary in character inspired its transportation to a new location occasionally, while the permanency of the others kept them in use to the bitter end. The old wooden toilets were open and exposed for fly-breeding, and in some instances where they were located on banks of streams they contributed directly to epidemics of water borne diseases.

The Commission has prepared specifications on toilet construction and insists on a rigid compliance with the provisions of the law in this particular. The Commission also interprets the law as requiring separate toilets for men and women, separately placed and properly marked.

Closely allied to the problem of insanitary toilets is the disposal of

garbage, rubbish and kitchen wastes. Many a countryside has been permanently defaced by piles of old cans, boxes, cartons and bottles, even after the storms and snows of winter have removed all traces of other wastes.

It is comparatively simple to meet the situation with covered receptacles the contents of which are emptied daily and either buried at a distance or burned in an incinerator. When camps are located on old ranches or when work animals are used in connection with the job, the problem of garbage and waste disposal is frequently complicated by the presence of large quantities of manure. One may visualize in terms of flies the result of establishing a camp in too close proximity to the corral. Of course there are two possible remedies in this case: one the removal of the manure and the other the removal of the camp.

#### Drainage and Sewage

Many of the kitchen wastes are in liquid form, which require more than covered cans for their disposal. This is true also of the waste from the bath-houses, wash-houses and from flush-toilets where they are used. When the camp operator is allowed to work out his own ideas of drainage and sewage disposal, the result oftentimes is the appearance of long, open, ill-smelling ditches and stagnant pools lined with refuse and breeding flies and mosquitoes. The solution in this case is found of course in a covered cesspool or in more permanent camps to a septic tank, a filter system or a chlorinator.

#### Where Responsibility Attaches

A labor camp laid out along the lines heretofore described may be a model plant today and a very disreputable establishment next week if

This picture tells the story of the insanitary preparation and service of food. Here can be seen the interior of a tent in which food is stored and prepared, with the cook's bed on the ground in the lower left hand corner. In the foreground can be seen the ever-present flies.

care is not given to its upkeep. The law would be a failure if there could be any doubt as to the persons responsible for securing compliance with its provisions. If it were possible for the owner to shift the burden to his lessee, the lessee to the contractor, the contractor to his superintendent and he to the employees, the result would be to negate the provisions of the law. Consequently it is made the duty of every "person, firm, corporation, agent or officer of a firm or corporation employing persons to work in or at camps to which the provisions of this act apply and the superintendent or overseer in charge of the work in or at such camps, to carry out the provisions of this act." And it is further required by the law that the responsible parties shall "appoint a responsible person to assist in keeping the camp clean." This work has now become one of the standard duties of the "bull-cook" and his helpers. Although the law fixes the responsibility in the operator, the Commission recognizes the necessity of developing cooperation on the part of the employees. Cards, bearing rules for camp sanitation, are furnished to operators to be posted about the camp. It has been found that workers of the better type go to the better camps, and generally speaking show a real pride in helping to preserve the higher standards.

The Commission of Immigration

and Housing is expressly directed to administer the act and to secure the enforcement of its provisions. For that purpose its inspectors are given wide powers of inspection, together with police power sufficient to carry out the penal provisions of the act. In the vast majority of cases it is not necessary to commence criminal action, although in cases of emergency, the use of a well placed fine or sentence of imprisonment has been found useful. This is true not only for its effect upon the individual defendant, but upon others of the same type in the neighborhood. In fact it has been found that drastic action against one especially flagrant violator of the law may have a very salutary effect upon many other operators in the same industry even in remote parts of the state.

The act also permits the abatement of camps as public nuisances, but this remedy has never been invoked up to the present time. The Commission is anxious to help rather than to harass the men who are carrying on industries, and the closing of camps would seriously delay operations. The method of procedure by criminal process is far more expeditious and does not in any way interfere with the progress of industry. The provision in the act is desirable, however, as conditions in a camp might become such a menace to health as to require the abatement of the whole plant.

The method of enforcement of the

law has developed slowly and has been based largely upon a policy of education. The inspectors are assigned to more or less definite sections of the state. They travel about from place to place, following the "seasons" and checking up on the conditions which they find. Their reports are sent in to the main office and letters are then sent out to the operators instructing them as to the changes which must be made to comply with the law, or in case of a sanitary camp, thanking the operator for his cooperation. In the case of a new operator, a copy of the Commission's Advisory Pamphlet on Camp Sanitation is sent to him. This pamphlet contains very complete instructions on the construction and maintenance of camps with diagrams and specifications covering all necessary phases of construction. The pamphlet has become so well known that many copies are sent out on request, not only to operators in California, but to large national organizations interested in camp construction.

Many times before the opening of a particular "season" the representatives of the Commission are called upon to address growers associations, farm bureau meetings and similar organizations, in order that proper plans and arrangements may be made. As the employees, on the other side, lack organizations it is generally impossible to meet them except in the camps. However, the camp laborer of California is well acquainted with the work of the Commission and calls upon it several hundred times a year for assistance. Many times these calls come in the form of anonymous letters. Sometimes they are inspired more by spite than by real grievances, but in every case the complaint is investigated and the identity of the complainant is never divulged. This has resulted in bringing in an increasing amount of information about insanitary camps. The following letter is typical:

'5 24 21.

"Housing Commission:

"Dear Sirs:

"There is a camp run by the \_\_\_\_\_ Construction Company at \_\_\_\_\_ in an unsanitary condition. Sleeping tents are overcrowded and without floors. There is no bathhouse, toilet not screened. The best time to investigate this camp is 5 o'clock p.m. as the men will be all here. Hoping you will investigate this as soon as possible,

"I am yours,

"For Sanitary Conditions."

The inspections, which follow complaints of this character, constitute only a small part of the total, and as a matter of fact four men are constantly at work. After the first inspection, if conditions warrant it, a reinspection is made. In the mean-

The interior of a warm weather camp with open screened sides. Pans of water under the table legs discourage the ants.

time instructions have been sent out from the main office at San Francisco, and if those instructions have not been complied with the case becomes a special order. If the operator shows a willingness to comply he is assisted and encouraged in doing so, and it is only in extreme cases that arbitrary action is taken.

The results obtained have been exceptionally good. The camp operators and employees alike are generally enthusiastic over this branch of the Commission's work and many letters are on file expressing appreciation for the assistance and instruction which has been given. The spirit of cooperation on the part of the employees has shown itself in increased efficiency and substantially reduced labor turnover. It is of course impossible to measure the results from a health standpoint, except to say that the improved sanitary conditions, in the light of what we know of the causes of disease and its spread, have undoubtedly contributed in a material degree to the state's improved health conditions.

The results have been nowhere more marked than in those cases,

The type of camp kitchen and dining quarters for which the California Commission has been striving and which is now common in the state.

few in number as yet it is true, in which the camp operators have gone beyond the requirements of the law and have built little cities of single family dwellings for their workers. The great weakness of the bunkhouse system is that it attracts the single man and continues the single man idea in industry. What California needs, especially in agriculture, is the encouragement of the family-man employee. This is being done to some

extent and with very good results. The contrast between the squalid living conditions of the Mexican worker in a bunkhouse or in his own shack, and his condition in a little home furnished by his employer is one which can be appreciated only by seeing it. Among the citrus associations of the state the custom of building camps of this kind is a growing one and it has prevailed for some time in the lumber, mining, and oil camps.

## The Physician and Workmen's Compensation\*

### Subjective and Objective Reactions in This Complicated Relationship

By GEORGE E. TUCKER, M.D., MEDICAL DIRECTOR, AETNA LIFE INSURANCE COMPANY, HARTFORD, CONN.

THE increasing interest in the medical administration of Workmen's Compensation Laws is evidenced by so many different important objective signs that the subjective symptoms might properly be ignored if they were not so forcefully over-emphasized.

The objective signs most easily recognized are:

(1) The large number of Amendments to the medical provisions of compensation laws that have been adopted in the several states during the recent sessions of the legislatures.

(2) The complete change of attitude on the part of the public, employers, and employees toward adequate and competent medical, surgical, and hospital treatment of workers injured in industry.

(3) The efforts of Compensation Commissioners so to administer the laws as to encourage proper treat-

*Hundred per cent earning power constitutes a much greater stimulus to good citizenship than does a limited two-thirds of wage pension and we will not believe that many American workers are ready to exchange their ability to work for any cash benefits that may accompany semi-invalidism and dependency under a compensation law.*

*A program that would deserve the indorsement and enthusiastic support of medical men is one that would furnish the services of skilled specialists as a preventive as well as curative measure and would employ modern diagnostic, therapeutic, and educational agencies for the rehabilitation of workers suffering from dismemberment or functional handicaps.*

ment of all injuries and to discourage payment of cash benefits in lieu of medical benefits.

(4) The emphasis that is now placed upon restoration of function and earning power, or rehabilitation.

The subjective signs of interest in the problem under discussion are the number of papers written, the opinions voiced by interested partisans as to details of proper administration, treatment, choice of physicians and other controversial features of medical administration.

Since physicians are trained to take histories, make examinations, weigh signs and symptoms, and make deductions in order to arrive at a diagnosis, prescribe treatment and go on record as to prognosis, perhaps the same method may advantageously be employed to present the case of the physician and Workmen's Compensation Laws.

The antecedents of our compensation laws in the United States were not unusually healthy. They suffered

\*Read before the New York State Association of Industrial Physicians, Syracuse, N. Y., December, 1921.

from numerous complaints that were readily transmissible, with the result that their progeny were not free from sundry and serious defects at birth.

The paternal ancestors migrated from Europe, being of mixed blood—largely German, English, and French. The maternal line was, at least for several generations, of native birth, but for many years not in good standing.

In other words, our early compensation laws were patterned after the German, English, French, and other European laws, with a trace of our Employers' Liability, or master and servant theory written into them.

### Personal History

There is an almost uniform agreement by legislators and parties at interest as to the purpose of Workmen's Compensation, both in Europe and in the United States. One would therefore conclude, without investigation, that there must be a corresponding uniformity in legislative provisions. On the contrary, even at this time, there is a wide difference of compensation standards in adjoining states, where those differences of industrial conditions that might affect requirements do not obtain.

If any possibility of uniformity of legislation in this country existed early in the enactment of compensation laws, such a possibility seems to be becoming progressively more remote. In fact Federal legislation, which would affect all states alike now seems like a development which is entirely outside the realms of probability. The inability to arrive at a satisfactory standard is presumably explained by the erroneous belief, now generally held, that there are marked differences in industrial and other conditions across state boundary lines.

It would be interesting, at least, to observe the results of an experiment which would apply the same compensation law in Massachusetts and Connecticut, or in New York and New Jersey, or in Illinois and Indiana. If the reactions were to prove essentially different and if society, including employer and employee, were, in consequence, to suffer or benefit differently across border lines, a wonderful field for social economic research would have been found—and the problem might properly be assigned to college professors for solution.

As physicians, however, and particularly as industrial physicians, our immediate interest is focused on those compensation provisions which relate

to medical aid and it is to this phase of legislation and administration that we must give our attention in this discussion today.

As late a study of this subject as is represented by the most recent publication of the United States Bureau of Labor Statistics<sup>1</sup> shows that of twenty European Acts reviewed (excluding the fifteen British Acts) eight have provided for limited medical aid or for none, eleven for unlimited aid, and one for unlimited after four weeks. Of the fifteen British Acts, thirteen make no provision for medical benefits.

If the fundamental promise actuating the passage of compensation laws and the discarding of right of action in accordance with employers' liability is sound, and if the burden of the employed who sustain accidental injuries—or as provided in some states, any injuries—arising out of and in the course of their employment, is to be distributed to the consumer through the employer as an added cost of production, then it would seem to follow that there would be uniform agreement that injured workers should be relieved of the cost incident to furnishing adequate first aid, intermediate and rehabilitating medical, surgical and hospital treatment.

Workers in industry exchange physical and mental effort for wages. In the case of workers who sustain injuries of some seriousness during employment there enters into production a temporary sacrifice of time, income, comfort, and physical efficiency. The public or beneficiaries of those efforts and sacrifices may, therefore, properly be called upon to meet the pro-rata and fair cost necessary to reimburse those benefactors for their loss of time and income, for their suffering and for the expense of such treatment as is needed to restore them, if possible, to their previous condition of mental and physical efficiency and earning power.

In spite of the apparent justice of this claim for equity and fairness as it affects both the injured and the consumer in the United States, of the forty-two states having compensation laws, but two have fully recognized it. Two others recognize it in part, and the others provide for limited medical aid or none, the limitations affecting time or money cost, or both.

The frequency of injuries resulting in dismemberment and the easy visualization of the immediate handicap

that such injured workers suffer should provoke sufficient public sympathy to bring about the incorporation, in every law, of a provision that will supply artificial members for such cases. But few states have such a provision and I will not undertake to offer an explanation for the legislative apathy, indifference, or poor conception of the real purpose of medical aid that has deterred such action.

Among legislators—and more to our shame, even among physicians—when medical aid provisions have been considered, palliation instead of restoration has been allowed to become the object of their efforts. The result has been that families are too frequently deprived of the support of their wage earners, an actual asset to society is permitted to become a liability and an otherwise profitable producer deteriorates into a helpless, consuming parasite.

Physicians and other parties interested in the compensation form of social relief in this country have made careful observations of the operation of compensation laws over a period of ten years. Their observations should have provided such incontrovertible evidence of the need for the continued broadening of the scope of medical treatment of injured workers, that the examples of unlimited medical aid, including artificial members, set by California in the West and Connecticut in the East, should have been followed by the other forty so-called compensation states in order that such states might conform to their standards of social justice and good business economy.

Legislators, however, must give consideration to the problem of acquiring votes and of retaining voting support with the result that their measure of legislative success is in part measured by a vote-getting standard. Physicians, on the other hand, if they would be successful, must attend to the problem of establishing and maintaining a professional reputation and to the equally important problem of commanding profitable financial return for their services. If the rewards necessary to bring the observations and information from the one group to the other were offered in their customary medium of exchange, the lure would have brought early response and more uniform legislation would have followed.

If you as a physician were delegated to provide that treatment to an injured worker suffering from a simple fracture of the neck of the femur

1. Bulletin No. 126; Workmen's Compensation Acts of the United States and Foreign Countries.

that would insure his recovery in a minimum of time with a maximum of functional restoration, would not a time limit of seven to thirty days, or a cost limit of twenty-five dollars to one hundred dollars operate to discourage both you and your patient? And would not the problem of meeting necessary economies and of providing adequate and proper treatment within those limits, take precedence over the question of how to restore that worker to full earning capacity?

The limitation of weekly cash benefits has not as a matter of fact, generally been so restricted. The measure of ultimate costs, therefore, resolves itself into a consideration of unlimited restoration expense as against prolonged payment of cash benefits, and no difficulty need be encountered in successfully defending the proper medical attitude.

### Health and Social Stimulus

Hundred per cent earning power constitutes a much greater stimulus to good citizenship than does a time limited two-thirds of wage pension, and we will not believe that many American workers are ready to exchange their ability to work for any cash benefits that may accompany semi-invalidism and dependency under a compensation law.

A program that would deserve the indorsement and most enthusiastic support of medical men is one that would furnish the following:

Immediate and intelligent first aid treatment for all cases of minor injuries.

Proper treatment of minor and major injuries of moderate severity.

The services of skilled specialists as a preventive as well as a curative measure.

The employment of modern diagnostic, therapeutic, and educational agencies for the rehabilitation of workers suffering from dismemberment or functional handicaps.

Many definite and practical benefits would follow the fulfillment of this program. The wastage of absenteeism and labor turnover would be reduced. Production would be increased and production costs would be lessened. Otherwise discarded human units would be salvaged. Mendicancy would be discouraged and the potential productivity of the injured American workmen would be afforded another opportunity to express itself in increased effort and added accomplishments.

And, if this reward were not sufficient, in many instances there are the

added benefits which would come unquestionably through the continued maintenance of the homes of those restored workers, through the education of their children and by reason of their contribution to the welfare, prosperity, and happiness of their fellowmen, their community, their state, and their country.

The anti-climax to the pronouncement of this ideal we might classify as constituting the subjective symptoms of interest in our subject. They arise out of the discussions of medical fees, the relative merits of different therapeutic procedures, the right of choice of physicians, the field of the general surgeon and the orthopedist, the ophthalmologist and the optician, the neurologist and the psychiatrist, the general practitioner and the specialist. The operating theory that has established physicians fees for the care of compensation cases has been predicated upon the assumption that the law was enacted for the benefit of those workers who come within its scope and for the benefit of society as a whole.

No emphasis, however, has been placed upon the need either for enacting or for administering the law so as to reflect a substantial financial benefit to the medical profession. On the other hand, no one knows of an instance where either compensation legislation or its administration has been designed to deprive physicians of any part of the income they previously enjoyed from the care of the same class of cases from among workers of the same relative income and similar financial responsibilities. Let it be shown that a greater benefit can be derived from more liberal allowances for medical fees, that insurance premium rates can be loaded to meet the necessary additional expenditures which would ensue and proper legislation will follow.

Any one privileged to review large numbers of compensation claims and charged with the responsibility of selecting men and institutions to treat claimants, would, I believe, make the choice primarily from among qualified ethical practitioners who obtain fairly uniform and satisfactory results. One would seldom question the methods or agencies utilized to obtain such results. It is not a question of *how* but *who* in a community can promptly restore flat feet, or remove embedded foreign bodies from the cornea leaving a minimum of after scar, interference with vision, or other complications.

Industrial medicine and industrial

surgery are as distinctly specialties within a group of specialties, as are brain surgery, gynecology, and orthopedics specialties within the field of general surgery.

The average layman, especially a sick layman, generally selects his physician for purely irrelevant reasons, but quite the contrary is the case when a physician selects a medical or surgical attendant, or more often a group of medical or surgical attendants, to treat a member of his family or himself. Education, previous training, and experience are most carefully weighed and a group of consultants is not infrequently asked to make the selection of a specialist when highly skilled services are required.

### Differential Diagnosis

The objective signs revealed by our examination show conditions so much more serious than those apparent from the subjective symptoms that we may safely eliminate certain possibilities from consideration. Since there is no uniformity in methods of administering compensation laws by industrial accident commissioners, it follows that of the several plans, some must be better than others. Ultimately, too, those having the responsibility will adopt methods which will improve their general results. The limitations of those improvements will be influenced by the provisions of the Act under which they operate, which leads us back to the original fault in the compensation plan for social relief that is, the imperfect understanding of its purpose by legislators and the faulty provisions that have been allowed to creep in.

The proper rating of permanent disabilities seem to be the most difficult problem falling to Industrial Commissioners for solution, and although one state has a fairly satisfactory plan, infinitely better than that of any other at present in operation, there seems to be some unexplainable hesitancy on the part of other states to adopt it.

If both the author's attitude and the previous statements and findings in this paper are sound, whatever shortcomings there are in the results obtained from the application of the compensation principle in this country and the part taken by physicians in connection with its operation may be attributed to faulty legislation and misunderstandings, and the cure will follow further study, investigation, education, and legislative amendments.

As physicians, we know that it is unsafe to prognosticate, but we may predict that if members of the medical profession will wisely interest themselves in the worker, the employer, and the body politic (being careful always jealously to guard the reputation which the profession has uniformly had—namely that its members will not under any circumstances prostitute their opportunities for service to the community to the furtherance of their own advantages), if they will intelligently gather information and place it before the proper parties at interest, if they will assist instead of resist, if they will criticize constructively instead of destructively and make their voices heard at the proper time and in the proper place, we may confidently look forward to the adoption of those changes in legislative provisions, particularly medical provisions, necessary to bring the greatest good to the greatest number.

#### Treatment Not Palliation

Palliative measures administered at regular intervals and directed toward relieving the symptomatology will, like a narcotic, obscure the real pathology and mislead the anxious bedside watchers. Genuine and permanent relief, however, will come from the employment of radical surgery and its application to compensation laws, from cutting out dead tissues wherever found, performing a debridement, so to speak, and the transplantation of live parts from healthy subjects.

Payment of cash benefits in amounts sufficient to reward idleness and penalize effort contributes to the moral delinquency of susceptibles and creates an immoral hazard against which neither state nor private interests can successfully insure. When the difference between full wage combined with a reasonable day's work, and two-thirds of wages combined with no work, amounts to so small a sum that the principal incentive to produce is removed, then we may expect the predominant human weakness—that is the irresistible impulse or temptation to get something for nothing—to assert itself. On the other hand, if cash benefits are so niggardly that they fail to accomplish the primary object for which they are intended, if they need to be supplemented from savings which do not—and in too many instances could not—exist, or if the benefits must be supplemented by charity, then their very purpose is defeated and no permanent good will result.

To reflect real benefit to industry, society, and workers, cash payments must be sufficient to insure a reasonable amount of food, clothing and a comfortable shelter for those injured and for their dependents. The necessity of suddenly precipitating wives and immature children into industry should be avoided, in order that society and the family unit may derive those benefits that come from the activities of women in the home and from the educational advantage that come to children in school.

If it can be shown that business interests of an essentially industrial state with large manufacturing payrolls have not, by reason of the enactment of legislation that provides unlimited medical aid for injured workers, suffered any handicap in competition with similar interests in an adjoining state where the medical provisions of the Compensation Law are less liberal in scope, the weakness of one of the most useful and most freely used arguments against unlimited medical benefits will have been demonstrated.

If those cases of injury requiring

special care and treatment are permitted to receive such attention in amounts no less adequate and in kind no less skillful than they enjoyed in free public hospitals at the hands of clinical staffs before compensation laws were passed, and if the same care and judgment will be exercised in the assignment of cases that was evidenced by the receiving staff of those same institutions, then and then only may we feel that they will receive the assistance then obtained during the presumably barbarous days of public disinterest and apathy.

Industrial physicians will protect their group of workers and ultimately other similarly interested parties will just as zealously and certainly afford the same protection to their own groups, so that finally the spirit that medical men, as well as employers and employees, can most profitably demonstrate toward social relief and social betterment, will place interest above indifference, industry above idleness, fairness above injustice, intelligence above intolerance, and service above self.

## A Remarkable Surgical Service

**A**SURGICAL service giving, through centrally located clinics, full time, free treatment to workers all over the country who sustain industrial accidents, treatment rendered by highly specialized industrial surgeons, supported by a body of the leading nerve, eye, heart, and orthopedic men of the Nation—that

is the aim of the Liberty Mutual Insurance Company in establishing and maintaining its chain of surgical dispensaries, according to an interview given to THE NATION'S HEALTH by George W. Morse, M.D., acting Medical Director of that Company and head of its surgical work.

Established in 1913, when its home

X-ray examination is a routine procedure in cases demanding it, both for purposes of diagnosis and for checking progress. In certain cases the pictorial record is the best possible report of progress and final result.

Good results follow consistent care. In the interest of rehabilitating the injured workman, treatment is extended for the full period of disability despite the time limitations permitted under the law in Massachusetts.

office clinic was opened in Boston, Mass., this unique service in which the Liberty Mutual was the pioneer, has grown from 4,084 treatments the first year to 58,193 treatments in 1920. This service is given without a penny of cost to the injured employees of its assured, and without regard for the statutory limits of medical treatment provided by the Workmen's Compensation Acts of the various states. "During my ten years of work with the Liberty Mutual Insurance Company," said Dr. Morse, "I have seen the Medical Department grow from a small clinic of two or three patients a day to one where hundreds of patients are advised, treated and sent back to work every day."

#### A Change of Attitude

When the Liberty Mutual Insurance Company opened its first clinic in a small apartment located some distance from the main offices of the Company, the few injured men who came there did so because they were told to by their employers. They were skeptical about everything. Too often they distrusted the doctor and had the idea that he was in league with the insurance company to heat them out of their just compensation. Time after time men would be sent to the clinic, where treatment would be given by doctors well trained in surgical work, who were graduates of the best schools and the best hospitals and, after receiving the treatment, they would go to the doctor near their factory—usually a man of little or no surgical experience—who would take off the dressings and ad-

vised the patient to stay at home under his care.

In order to eliminate this element of distrust among the injured, it was essential to make the treatment afforded by the Company the best that could be obtained. Service was the slogan. No patient treated was given a chance to tell his fellow workmen that he did not get the best of treatment. In this way it gradually came about that in nearly every room of every plant insured by the Liberty Mutual there was at least one man whose lasting friendship had been won by the Medical Department of the Company, and who advised each injured man to go there. Gradually the attitude has been changed. The

clinic grew to such proportions that it became necessary to open others and the present chain of clinics gradually evolved.

"The attitude of the general practitioner toward this supplementary service has changed also," said Dr. Morse. "In this age of specialism the general practitioner has learned, sometimes by costly experience, that oftentimes in cases of sepsis, tendon suture, and fractures, special facilities are required to obtain satisfactory results. The requirements of medical practice under Workmen's Compensation have necessitated more complete records on the part of the physician and consequently a better check on the results obtained. There is no way of checking up how many avoidable sacrifices of members could be charged to neglect or to errors of judgment in the past, but the influence of careful record keeping and the certainty of a minute review of the conduct of compensation cases is conducive to more precise work on the part of the attending physician and, rather than err in technic or judgment, such revision prompts the general practitioner to avail himself of the special assistance that better medical organization under Workmen's Compensation has made possible."

This improvement has affected the medical personnel of insurance companies as well. Originally the insurance doctor, so-called, was looked at askance by the medical profession as a whole and everything he did was subjected to suspicious scrutiny. The requirements of Workmen's Compensation have evolved for the insurance

Physiotherapy has proved a valuable adjunct to the restorative measures employed. The equipment is complete and up to the minute.

doctor a definite and important function in the community. The old causes of adverse criticism, fundamentally a misunderstanding on the part of the profession at large of the attitude of the insurance company, has given way before their collaborated effort.

Under present conditions, requiring their mutual activity, many defects in medical organization have been remedied. Unbelievable conditions resulting from neglect and ignorance under the old system were brought out in the early days of compensation. Infections were neglected until amputation was the only recourse. Tendons were left unsutured and the injured members hopelessly crippled by delay or mismanagement. Fractures were not recognized,—all this sometimes from lack of skill on the part of the attending physician, but oftener for lack of facilities which are now available and have come to be regarded as essential.

Another striking defect of ante-compensation days was the dearth of records kept by the medical profession. Time after time the records necessary in a given case were lacking. These conditions have changed and it is now the exception to find a full report lacking when it is required. Accurate, even pictorial records are usually available, and in most cases evidence of consistent care is manifest in the collaborated effort of several specialists in difficult cases.

In order to influence the injured workman to go to the clinics, the Liberty Mutual not only offers the best of treatment, but free treatment is given for the entire period of disability, although in Massachusetts only two weeks' treatment was obligatory under the Act. As every day of disability meant a loss of compensation to the Company, and as every finger or hand lost meant additional loss to the Company, it was the business of the Medical Department to see to it that every case received the best possible treatment and the concise records in the claim folders of each case revealed at once to the officials of the Company, the employer, the Industrial Accident Board, as well as to the man himself, any cases where bad results were obtained.

As every doctor in the clinic knew that his records of the case would probably receive the visé of many critics, it tended to make him careful to do his very best for each man. Moreover, if he gave an opinion, he knew that there would come a time when he would have to substantiate

it with his reasons for it. These factors tended to make the average doctor even more careful than the training in the out-patient departments of the big hospitals.

Having gone through the various phases of training, the Liberty Mutual now has a large floor in its home office building devoted to the clinic. The clinic is open from 8:00 a. m. to 6:00 p. m. Doctors and nurses experienced in this work are in attendance during this period, and accurate records are kept.

In connection with the clinic room there is an x-ray room, and a room for baking and massage, as well as consulting rooms, and rooms for sterilization, etc. The staff is made up of the medical director, who acts as a consultant and administrator, five doctors who are on clinic for two hours each during the day, a nurse, a roentgenologist, a masseuse, and the necessary stenographers and record clerks.

The department also has a consulting orthopedist, an eye specialist, a nose and throat specialist, a skin specialist, a neurologist, and a man trained in the field of industrial poisoning.

Supplementary to the clinic at the home office, the Liberty Mutual has arrangements with the Brooks Hospital, one of the finest private hospitals in the country, where cases re-

quiring operation and hospital care may be sent to receive all the advantages of an up to date, modern hospital. This hospital has been a great asset to the Company, as the injured employees have been pleased with their treatment and the results so uniformly satisfactory that all remnants of distrust have been dissipated. In other words, during the last ten years the treatment of injured employees has been wonderfully improved, the period of disability has been shortened and the workmen have learned that the company's aim is their aim; that it is the aim of both to prevent accidents and, if accidents happen, to get the best treatment, the best results, and get the employee back to work as soon as possible.

The treatments at surgical departments each consecutive year ending December 31 show the growth of the clinic, as follows: 1913, 4,084; 1914, 5,063; 1915, 8,994; 1916, 15,894; 1917, 23,475; 1918; 25,818; 1919, 53,368; 1920, 58,193.

The aim of the Medical Department is to shorten the period of disability and to restore the man's earning capacity as soon as possible. It is the policy of the Company to pay for the treatment which will do away with the man's disability, rather than to pay the injured man compensation for a long period.

## Recent Compensation Decisions

THE California District Court of Appeal April 27, 1921, has also passed upon the matter of the liability of the hospital for the negligence of its servants. The case is not given in full, but part of the opinion is cited.

The defendant was a corporation commonly known as the French Hospital of San Francisco. The hospital appealed from a judgment after a verdict in favor of the plaintiff, which was rendered in an action brought by the plaintiff to recover damages for the death of his infant child. These damages were caused, it is alleged, by the child's being fatally burned while an inmate and under care of the hospital and is predicated upon the alleged carelessness and negligence of one of the student nurses of the hospital who was placed in charge of the child by the hospital superintendent. The trial was by a jury, which rendered a verdict in plaintiff's favor in the sum of \$5,134.

The child was ill with bronchial pneumonia probably induced by influenza. Oxygen was being administered and the child was cyanotic. The mother remained with the child and before leaving attempted to secure the services of a trained nurse. Two student nurses in training volunteered to care for the child.

"One of the nurses took the patient until midnight when the other relieved her. The child had great difficulty in breathing, and an awning was constructed over its bed, within which was placed a lighted alcoholic inhalator, containing eucalyptus oil, the purpose of which was to diffuse a vapor which would relieve the respiration. About 3:30 A. M. the nurse then in charge left the room where the baby was lying for a few minutes. When she returned she found the bedclothes on fire. She lifted the child from the bed; the fire was extinguished and a doctor was immediately summoned, who administered first aid.

There is an irreconcilable conflict in the testimony as to the extent and nature of the burns the child received. Doctors and nurses who saw the baby after the fire testified that the burns were, for the most part, slight, first degree burns, limited to the face, one knee, and the arms. The parents of the child and the undertaker who prepared the body for burial testified that the burns were very deep, extending over more than one-third of the body. The child died some 16 hours after the fire. Whether or not her death was due to the effect of the burns, or to bronchial pneumonia induced by influenza, is one of the issues of the case.

(1) It is first contended by the appellant that the act of the nurse in caring for the child on the night of the fire was purely voluntary and an act of mercy, outside of her regular duties and did not come within the scope of her employment by the defendant, and was something which the hospital in no way could have required her to do, and from which it in no way profited. On this ground it disclaims any responsibility in the premises. We think, however, that there was no mere unwarranted assumption by the nurse of a duty not assigned to her, but that she was directly engaged within the scope of her employment in caring for the patient and ward of appellant, and with the authorization on the part of the appellant as to amount to an assignment. Consequently, appellant is liable for all actual damages resulting from the nurse's negligence.—*Languy v. La Société Française de Bienfaisance Mutuelle*, 198 P. 1011.

THE question of the liability of a hospital and of its insurer for the negligence of its servants has been passed upon by the Supreme Court of Nebraska, June 23, 1921. It was there held that where a child born in a hospital is returned thereto three months later to receive nourishment from its mother, who had previously returned for treatment of ailments attending childbirth, the child, while in the exclusive care of the hospital is a "patient," and not a mere licensee, the arrangement being that compensation for the treatment of the mother includes compensation for the care of the child.

In a hospital with a department equipped for obstetrics, the bathing of a child born therein, if it thereby suffers bodily injury through the negligence or the mistake of a hospital nurse while it is exclusively in

the care of the hospital, may be "hospital treatment" within the meaning of those words used in a policy of liability insurance.

A nurse makes a "mistake" within the meaning of a liability policy insuring a hospital against liability "in consequence of any malpractice, error or mistake," when she allows the hand of a helpless child to come in contact with a hot appliance.

Judge Rose delivered the opinion of the court:

This is an action on two insurance policies, each for \$5,000, to recover the amount alleged to be due from the insurers for a loss reduced to a judgment for \$5,000 which Mary Jane Hannah, an infant, recovered against the Ford Hospital Company, the insured, in a former action for personal injuries. (One of policies was issued by the Fidelity and Casualty Company and the other by the Maryland Casualty Company. Both are defendants, and insured is plaintiff herein. Each insurer, referring to its own policy, pleaded among other defenses, that liability for the negligence resulting in the personal injuries to the child was not covered by its insurance, and that it was not bound by the judgment for damages.) After the evidence had been adduced in this action on the liability of the insurance policies, each party requested a directed verdict in its favor. As a result the trial court exercised the jury and entered judgment in favor of the Ford Hospital Company against the Fidelity and Casualty Company for the face of its policy, or \$5,000, for interest amounting to \$120.83, and for an attorney's fee of \$400. The action was dismissed as to the Maryland Casualty Company. The Fidelity and Casualty Company has appealed.—*Ford Hospital v. Fidelity and Casualty Co. of New York*, 183 N. W. 656.

WHERE the employees of a railway company formed a beneficial association, which built and equipped hospitals, the administration of which was in the hands of persons elected by the employees, a small percentage of each employee's salary being collected by the railway company and turned over to the Association, the association was not the railway company's agent in treating members, and the company was not liable for negligence in such treatment, although it contributed \$50,000 a year toward the success of the hospitals, and its treasurer and comptroller of the association, and persons

not members, injured on the road, were sometimes treated at the hospital at the company's expense.

A conductor for the Northern Pacific Railway Company brought action against the Railway Company to recover for personal injuries alleged to have been suffered by reason of an operation for appendicitis performed by the chief surgeon of the Tacoma Hospital of the Northern Pacific Beneficial Association. When he became sick, Carr went voluntarily to the Hospital of the Northern Pacific Beneficial Association. The result of the operation was unsatisfactory and he charged that the defendant who operated was negligent, and the attendants furnished by the defendant were negligent in not doing certain things they should have done—*Carr v. Northern Pacific Ry. Co.*, 273 Fed. 511 (U. S. Circuit Ct. of Appeals, May 21, 1921).

THE Supreme Court of Connecticut has recently held that where the evidence showed that an employee fell from an open doorway protected only by a bar, when he went there to get fresh air, because the account of an operation given by the superintendent had made him feel faint, and that he fainted when he reached the door and fell out under the bar, the injury did not arise out of his employment, within the compensation act, although his employment permitted him to go to the door at that time, and though it would be inferred he went for some purpose connected with his employment, if the uncontested finding did not show the contrary.—*Reeves v. John A. Dady Corporation*, 113 A. 162.

THE Supreme Court of California, August 15, 1921, declared that the findings and conclusions of the Industrial Accident Commission on questions of fact are conclusive if supported by substantial evidence, and cannot be reviewed by the Supreme Court *in certiori*, under Workmen's Compensation, Insurance and Safety Act of 1917, Sec. 67 (a), 67 (c).

A garage employee was repairing tires when he was struck by a bullet from his employer's gun. The bullet was intended for a stranger with whom the employer had a controversy over the purchase of gasoline, resulting in the shooting by the employer to defend his business. The Court held that the employee sustained an injury "arising out of and in the course of the employment."

within Workmen's Compensation, Insurance and Safety Act of 1917, Sec. 7 (a), in view of section 69 (a), though the accident was unusual and was not anticipated nor peculiar to the occupation. The case is unusual and constitutes an interesting decision.

Quoting from page 421, "The injury sustained by (the employee) was not due to skylarking or a frolic, but was received in the course of a series of incidents which had their initiation in a business transaction of his employer and while the latter was

actively and justifiably engaged in defending his business. . . . When Barr (the employer) began shooting, he voluntarily exposed ShROUT (the employee) as well as all other employees to the danger of being shot, and the fact that the injury which resulted was unintentional and purely accidental does not, in our opinion, prevent ShROUT (the employee) from recovering."—*General Accident Fire and Life Assur. Corporation v. Industrial Accident Commission*, 290 P. 419.

tion of an officer does not cease with drill and the administration of his organization. He must develop and upbuild the character of his subordinates for here lies the efficiency of the group. The officer should be fair and willing to accept criticism and criticize himself.

Personality and leadership have occupied attention not only in the military but in civilian fields as well. The author here conceived leadership as the creative and directive force of morale. "The success of any army in peace or war, or the functioning of a great industrial establishment, depends very largely on the human leadership and ability of its superiors. The mere holding of a commission does not make an officer a leader. It assumes that he is a leader but it is further necessary for him to prove that he is one. The responsibility of leadership includes not only the officer but extends through him and beyond him to his men." Efficient leadership is based on a knowledge of human mind and morale factors. "To inspire faith is to give ability to accomplish."

It is impossible here to give the wealth of material which this keen observer of contemporary society has gathered together, prudential in fact, but nevertheless of great value in the absence of more exact psychological or philosophical data. The army affords really a most significant opportunity for the observation of society, a controlled society consisting mostly of young men but nevertheless with endless possibilities of experimentation.

The book here reviewed contains for example a chapter on "reward, punishment, and delinquency," giving some very illuminating data, more available perhaps than in ordinary life.

The chapter on industrial morale relates and is based upon the efforts to stimulate munitions work. The factors of industry, absenteeism, the importance of leadership, etc., are all discussed. It is pointed out that improved facilities for the hearing, investigating and remedying of complaints might decrease much of the labor turnover. "Encouragement succeeds where driving fails. Appreciation causes a sense of creative pride, which brings not only the hands but the personality to the work. What is needed is a spirit of service—not of servitude"—applicable it may be added to both sides, equally and at all times.

Henry Holt & Co., New York, 1921.

## The Management of Men

THE management of men with the more closely regimented systems of life is an increasingly important problem. The purpose of "Management of Men," by Edward L. Munson, is to develop the idea that management and morale is a science "whereby mental state and human behavior can be comprehensively and effectively controlled by the scientific application of the fundamental laws governing human nature itself." The problems and solutions offered in this book were worked out for the army. The principles, it is suggested, may be applied to industrial morale "and these should go far forward toward the solution of the disturbing economic, social and political problems springing from human relations in industry." The question as to what is a science and how far the solutions offered are acceptable will, for the present, be waived.

Morale is defined as "fitness of mind for the purpose in hand," "a sense of solidarity of strength and purpose, and ability to undergo in the accomplishment of a common cause," to continue after everything else is gone, the will to power, conquest or what not, misnamed a state of faith. The purpose of morale work is to make troops effective. It may be defined as positive or negative in character qualified as the case may be by self control, persistency, tenacity and initiative, or conversely by discouragement, dissatisfaction, and inefficiency. Patriotism and love of country are designated as the basis of military morale, capable of perversion for selfish ends, of course, but also pointing a way to higher things, freedom, democracy, and self-determination.

Morale work can, as everything else, be standardized. Methods and measures are susceptible to change but a minimum can be extended.

Morale work endeavors to secure and furnish systematically information of the scientifically successful methods of handling men. In its application the individual or group must be studied to determine natural tendencies and habitual reactions, personal and human factors. Remedial action may be effective one time and fail another. Methods to arouse pride in service, to develop interest and enthusiasm are suggested; lectures, posters, slogans, parades, etc. Everything entering into the mind or environment of the soldier and his associates, civilian or military affects his morale, some tending to raise, some to lower it. Poor morale is said not to exist without a reason? Is the converse true? All morale work should be carefully planned, which is of course axiomatic and scarcely confined to any branch of knowledge.

General psychological principles, the basic instincts, fear, hunger, imitation, construction, etc., all have their place in the discussion. Psychological qualities, relations and methods, temperament its relation to sympathy, racial and individual traits, mood, character, habit, suggestion and prestige are all developed.

Officers and higher business officials may be said to be the controlling factors in the development and maintenance of military and industrial morale. The commanding officer, the morale officer, the chaplain, the company commander, and others all have very definite duties and obligations. No amount of technical training and knowledge will make an officer really efficient if he cannot preserve harmony and get the best out of his men. There are right ways and wrong ways of handling men. The army method is that of a command. The officer must be able to reach and inspire his men, while the giving of orders is an art in itself. The func-

## Ohio State University Student Health Service Prevention of Disease and Health Preservation Are Keynote of Work

BY H. SHINDLE WINGERT, M.D., DIRECTOR STUDENT HEALTH SERVICE, OHIO STATE UNIVERSITY, COLUMBUS, OHIO

OHIO State University, with an annual enrollment of over 8,000 students, is composed of twelve colleges, among them, the College of Medicine, the Homeopathic Medical College, the College of Pharmacy, and the College of Dentistry. It is centrally situated in Columbus, a city with a population of 237,000, containing sixteen hospitals, and an unusually large number of practicing physicians, surgeons and specialists. The university has, therefore, an advantageous position for cooperation in medical and surgical work for her students. The Students' Health Service has also so many sources of assistance available within the campus that our working policies have been formulated quite differently from most other Health Services in colleges.

The Students' Health Service occupies the entire first floor of the west end of Hayes Hall, which is located centrally on the main oval of principal buildings near the entrance to the campus and in close proximity to the Physical Education and Athletic Departments. The rooms are ample in space, lighting, and arrangement for service; an extra large waiting room, a capacious consultation room, and quiet operation and rest rooms. The equipment is first class in every particular. Our present Student Health Service Department is the outgrowth of the Medical Emergency Section which was organized in the Physical Education Department in 1908, and continued as sectional work until 1915 when it was established as a separate department.

In formulating our working poli-

*The time to teach health truths is during illness or epidemics. This is the psychology at the basis of the health education program of the Ohio State University Student Health Service. Healthy students show little interest in lectures on how to keep well, but when sickness overtakes them, then the information has direct personal bearing.*

*Making disease-prevention work personal at times of epidemics or individual illness has been found to be a most effective means of health education. The aim of the Student Health Department has been so to develop its service that the student will continue to apply the principles of "Health First" to his life even in after-college years.*

cies, we tried to avoid anything that resembled State medicine, health insurance, or paternalism. We decided (1) to devote the major part of our time to the preservation of health and the *prevention of sickness*; (2) to endeavor at all times to foster and maintain the cooperation of the various colleges and departments in the University, and other agencies on and off the campus, which are operating for the health betterment of the university and community; (3) to recognize the rights of students to select their own physicians; (4) to make

the individual student the center of intensive study, rather than the student body as a whole; and (5) to develop a type of service which would leave a lasting good impression upon the student, so that he might continue to apply the principles of "Health First" to his life in after-college years.

In adopting these policies it was necessary to find the best methods of impressing the average college student that "health care" pays; that the early attention to trivial ailments often saves many valuable college hours. Though our lecture courses on personal hygiene help, one need not lecture long to young, healthy college students (and those who think they are well), on how to keep well, to find out how uninteresting it is to most of them. But when epidemics occur or sickness overtakes them, they are quite different persons. We long ago determined that to do the most effective work in disease-prevention, it must be personal, and at a time when the student is interested in his personal health and comfort. The methods we have been using in the past five years we believe have been very successful.

Medical advice and treatment are furnished free to students while they are on the campus during class-hours. In all cases of outside calls for medical attendance it is first ascertained if the patients have any choice of physicians. If not, the calls are referred to physicians in whom the Service has full confidence. We do not make calls or treat students outside of class hours. The department

Ohio State University campus, showing central location (x) of Hayes Hall, in which the Student Health Service maintains headquarters.

acts as a clearing house for sickness and accidents occurring on the campus. Students who are compelled to remain away from their university duties on account of sickness, report here before and after the attack when possible, and are provided with excuses for their absences. In this way we are able to keep in close touch with the general health of the University students.

### Monthly Health Reports

From the opening of the University in the Fall, until early Spring, a constant health propaganda is conducted by monthly reports to the teaching force, through the University daily paper, and by distribution of our "Health Cards." The student is at all times impressed with the importance of prompt treatment of trivial ailments, both from the standpoint of the individual student, and from that of the student community.

The growing interest in this respect is shown in the following statistics: 1918-1919, office calls for *advice only*, 135 patients; 1919-1920, office calls for *advice only*, 259 patients; 1920-1921, office calls for *advice only*, 446 patients.

When the student appears in this department, he is required to fill in certain blanks. He is then ushered into the treating-room, his case diagnosed and treated. He is then given personal advice concerning *care of himself during his present sickness*, and presented with our Health Cards, showing *how to prevent a recurrence of the same*. When the case is serious enough to require the student to remain in his room, he is assisted in every possible way to secure the proper medical attention or hospital care. In this way we secure the student's lasting interest and cooperation.

Last year 3,595 different students made a total of 10,923 visits to this

department. The prevailing diseases were coryza, nasopharyngitis, tracheitis, bronchitis, and disordered digestion. There was very little serious sickness; in fact, there has been a steady improvement in student health from year to year, with the exception of 1919, during the "flu" epidemic.

Through the hearty cooperation described below, we are able to conduct our work with a remarkably small staff,—one physician, a nurse, and a secretary. The largest number of patients treated in any one day, in October, was 104, the smallest number, 64, average number daily, 85.

### Cooperation by Many Agencies

It may be hard to understand how this volume of work can be efficiently handled by such a small staff until one has become acquainted with our Health Card system, and the cooperation of other departments. This department is not attached to any college in the University but is under the direct supervision of the President. The annual expenses, which

are extremely low, are paid by the Trustees out of the general funds of the University. Cooperation is secured through: (1) College of Medicine by daily clinics open to all students; Department of Public Health and Sanitation, regular credit courses in Personal Hygiene, Preventive Medicine, Social Service, and Public Health Nursing; (2) College of Homeopathic Medicine by daily clinics open to all students, with laboratory and x-ray assistance to this department at any time; hospital accommodations to students at low rate; (3) College of Pharmacy, which conducts a dispensary especially for the department, open daily during class hours; they fill all our prescriptions and furnish medical supplies at cost to students; (4) College of Dentistry by daily clinics open to all students, all kinds of work being done, for which a small fee is charged; (5) Department of Applied Optics by clinics open to students four afternoons a week; eyes examined and prescriptions given free; students applying for relief from eye trouble, caused by constitutional diseases, are frequently referred to this Department.

Further cooperation is secured through other departments, student organizations, and state and city health agencies. All men entering the University for the first time, and all women of the first and second years, are required to undergo a thorough physical examination by the Department of Physical Education. Records of these examinations are available to this department at any time by phone or letter at the shortest possible notice. This frequently

The waiting room where preliminary blanks are filled in.

helps us clear up a doubtful diagnosis and saves much valuable time. Accidents and acute illness occurring in this department are frequently referred to us for treatment. Its credit courses in Personal Hygiene are proving very helpful. All excuses for absence from military work caused by accident or acute illness are referred to the Student Health Service before the excuse is granted by the military authorities. Sickness and accidents occurring among students while on duty are referred here for advice and treatment.

Under the supervision of the Dean of Women, a periodical inspection of housing conditions for women is carried on. This includes cleanliness, heating, lighting, and ventilation of rooms, which is proving very helpful and is much appreciated by women. The Student Council has become deeply interested this year in our "Health First" movement, and has inaugurated a plan for the betterment of rooming and living conditions for our men students, which will surely bring good results. The University Y. M. C. A., through its health committee keeps in daily touch with this Department and visits students who are discouraged or too ill to attend classes and need help.

The State Department of Health Laboratories aid our work by promptly examining all specimens of sputum, smears, etc., and furnishes us with certain vaccines free for students. The City Board of Health also furnishes certain vaccines and investigates all suspicious cases of contagious diseases, and keeps us posted on the general health in the University district. City physicians, those especially in the University dis-

Minor surgical and electrical treatment room.

trict, keep us posted concerning seriously ill students under their care. We also note that members of the teaching staff are sending more students to this department each month for early treatment of trivial ailments. This is very encouraging, and helps to prevent a great deal of sickness. Through the cooperation of these various agencies, a number of valuable relationships have been established which are proving helpful to all concerned.

If there can be any criticism made on our present-day methods of handling Health Service, in universities and colleges, it will be from the standpoint that we are devoting too much time and money in treating disease and not enough in *preventing* it. Most of us agree that at least 75 per cent of the sickness which occurs during college life is preventable, and we believe the time is rapidly approach-

ing when "Health Care," instead of medical care, will occupy the major part of our efforts in our Health Service work.

### Mortality Rates Show Slight Increase for 1920

A slight increase in the mortality rate for 1920 as compared with 1919 is noted in the Census Bureau mortality statistics report for 1920. The 1919 rate of 12.9 per 1,000 was the lowest on record since 1900, the 1920 rate being 13.1 per 1,000. Fears that the increase would continue during 1921 are allayed by statements indicating that for the first nine months of 1921 the recorded mortality was 18.1 per cent lower than in the corresponding period of 1920.

The death rate from pneumonia increased from 123.5 per 100,000 in 1919 to 137.2 in 1920; organic diseases of the heart from 131 to 141.9; cancer from 80.5 to 83. Measles, scarlet fever, whooping cough, automobile accidents and cerebral hemorrhages also showed increased rates. Tuberculosis shows a marked decrease from 125.6 per 100,000 in 1919 to 114.2 in 1920, also influenza from 98.8 to 71.

The almost steady decline in mortality rates is largely due to the lower rates from tuberculosis, typhoid fever, and other communicable diseases. Application of the known principles of disease prevention, advances in our knowledge of the cause and treatment of disease, and a consistent steady campaign of popular education in personal hygiene will bring the mortality rates nearer the irreducible minimum which is the ultimate objective of a preventive program.

Consultation and treatment rooms.

# Sanitation in Public Buildings as a Health Factor

## Conditions in Schools, Hotels, Jails Have Direct Community Health Bearing

By MANTON M. CARRICK, M.D., STATE HEALTH OFFICER, DALLAS, TEXAS

THE public buildings of our communities are important factors in determining the physical and mental health of our people. A healthy people physically is a healthy people mentally and morally as well. The two go hand in hand, and a weakening of one means a weakening of the other. Sanitary surroundings largely determine the healthfulness of a locality. Just as ignorance, indifference, and carelessness are the chief causes of preventable sickness and death of the physical man, so are low ideals and surroundings the social bacteria that prey upon the mental associations.

The most valuable asset in the capital of any community is the health of its children, and as nearly all children between the ages of seven and fourteen years attend school, it devolves upon the community to see that their surroundings while in school are conducive to their well being, physically, mentally, and morally. It is the duty of every parent to know the school which his child attends, but how many of them have never seen even the inside of the building?

### Sanitation in Schools

If children are in a crowded school building they are in an improperly ventilated one, and are not doing their best mentally. Every school room should be constructed so as to give each pupil at least four hundred cubic feet of air, and this air should be entirely renewed every half hour. In cold weather the air should be thoroughly heated and an adequate supply of fresh, warm air be constantly introduced into the room. It should be borne in mind that cold air is not necessarily fresh air.

Sunshine should be the architect's rule in constructing a school house. School rooms with the windows placed in the north wall are best, as they are more uniform, and the desks, which must be suited to the size of the child, should be arranged so that the light will come from the left side and the rear. Sunshine and adequate heating facilities will do much to eliminate the dampness, commonly found in many schools, which

is so inimical to mental and physical health.

The toilet rooms of our school buildings present a problem that is crying aloud for solution. The closets should not be connected in any way with the school rooms. In schools where there are no sewers, the toilets should empty into specially constructed tanks to dispose of the sewage in a sanitary manner. The best urinal is of slate with the dry earth system of disposal. In cities where there are sewers, the closets should have automatic seats to secure prompt flushing. Every toilet room should be provided with a lavatory to preserve health and cleanliness, and floors, walls, and fixtures should be scrubbed daily with water containing a disinfectant solution.

Parents should inspect with particular care the water supply of the school. Pure water is essential to good health. Sanitary drinking fountains should be installed in all school grounds as the expense is small and the sanitary valuation is immeasurable. They should be located on the play grounds. Like every other part of the school, these grounds should be kept scrupulously clean. Nothing should be allowed to clutter up the place; refuse and garbage of all sorts should be deposited in covered receptacles which should be emptied and cleansed regularly.

Care of the child health of a community is truly casting bread upon waters—it returns as a thousand-fold blessing in the shape of healthy citizens, intellectually alive and forceful. But a community may have ideal schools; the children may be models of hygienic attention; and the outside world will still shudder at mention of its name, all because of the hotels.

### Sanitation in Hotels

A hotel may be the measure by which a whole town is judged. It is the home the town offers to the traveler within its gates. If it is dirty, unattractive, insanitary, it reflects upon the entire community. Public spirited men and women should realize this and should see that its hotel dishes are properly washed and wiped, and should make certain that

what I sometimes have found—dishes washed and not wiped, dishes wiped and not washed, dishes neither washed nor wiped, but doing a second, even a third time service, is not the condition in hotel kitchens of their town.

Bed rooms also should be inspected. Cuspidors overflowing with week-old deposits of fruit peels, tobacco, paper, and other trash should be noted. Only too often are the mattress and blankets on the bed in a highly uninviting condition. Woodwork and floors should be disinfected often.

To insure fresh air, every room should be aired daily, and bedding in rooms should be aired frequently when these rooms are not in use. Transoms should be placed over every bed room door and the halls should be well lighted and aired. Sunshine is one of nature's greatest boons. "While there's life there's soap," and soap should not be spared in keeping the hotel shining with cleanliness. Not only should the floors be swept daily, but the walls should be gone over at least once a week with a cloth to remove the dust, for germs are not confined to the dust on the floors alone. In sweeping, a good sweeping compound is made by wetting a pailful of sawdust with water and adding one-half of a pint of kerosene and a teaspoonful of suphonaphthol or a 4 per cent solution of formaldehyd. This prevents dust being stirred up and acts as a disinfectant also.

Hotel sanitation is a problem that the health authorities must handle, but the citizens of every city and state should agitate it until a reform in the manner of conducting these places is brought about. It affects the health, not only of the community in which the hotel is situated, but also the health of every community from which it draws its patronage. We must agitate a rigid enforcement of the laws of sanitation which are, after all, the laws of common sense and common cleanliness.

### Sanitation in Hospitals

The hospitals, particularly the county hospitals, offer problems in municipal sanitation. The application of modern sanitary principles

and the installation of approved sanitary appliances, which are necessary even in the case of ordinary dwellings wherein only a few healthy persons are sheltered, become of paramount importance in the case of sick and helpless patients.

The two great general sanitary requirements for hospitals, whether large or small, are, first, plenty of light and fresh air, particularly for the wards, for the toilet rooms, the pantries, and the closets; second, absolute cleanliness inside as well as outside of the buildings. A perfect system of water supply, sewerage, plumbing, and ventilation will help considerably in securing both conditions.

Water supply and sewerage are closely allied. No hospital, having a general system of water supply, should be without a sewerage system, and on the other hand, every hospital provided with sewerage facilities requires an abundant water supply to secure the flushing out of the plumbing fixtures, waste-pipes, and sewers. An abundant supply of good and pure water is a prime necessity. More water is required for hospital buildings than for other institutions in order to secure the fastidious cleanliness characteristic of a good hospital. Not only must provision be made for the large volumes of water required for personal cleanliness, for bathing, scrubbing, use in the laundry and boiler-house, but a large surplus of water is required for fire protection purposes. To insure the purity of the water used in hospitals the following analyses should be made: Chemical analysis to determine vegetable and animal impurities; a biological analysis to determine the number of disease germs, if any, and the bacteria present; and a sanitary inspection of the source of supply and its surroundings.

In a well-managed hospital, then, the most thorough cleanliness and a pure condition of the air indoors are secured by a constant vigilance against all manner of dirt. Half the battle is won when the buildings have a good system of sewerage and plumbing. These will not only prevent a contamination of the atmosphere in the toilet rooms, lavatories and sick wards by emanations from the sewer pipes and plumbing fixtures, but they will also render it impossible for the soil upon which the building stands to become polluted and give off gases injurious to well people and fatal to sick ones. They will, finally, assist in the maintenance of absolute cleanliness of the walls

and floors, of personal cleanliness, and purity of the water and food supply of the hospital.

Court houses are nearly always unsanitary. Tobacco quids and stains on the stairways and in the corridors seem to be inevitable. The courthouse is the center of much of the activity of the county and should be a clean place, its spotlessness indicative of the type of justice to be dealt with therein. But too many of our court-houses are foul with accumulated filth and bad odors and it is hard to believe that any judge or jury could render impartial verdicts in such surroundings.

Sunlight and soap are all most of these buildings need. A washing of dirty windows and stained walls, and a touching up of grimy furniture will transform the place from an obnoxious one to a pleasant habitation for the officials who occupy it. A judicial "jerking up" of the janitor would, no doubt, result in a lavish and much needed use of mop and broom.

#### Sanitation in Jails

From the courthouse is but a step to the jail, one of the greatest problems of our community life. Jails as breeding places of crime is no new thought, but jails in a considerable number of communities are a menace to the life and health of your family. Jails are sad places at best; that the inmates are there may not be our concern, but how they are cared for while there, is.

I have visited jails remarkable for their filthiness. Many of them are in perpetual gloom because of inadequate lighting facilities, and on the damp walls, vermin breed. Rat-infested and bat-plagued jails are commonplace, and rats and bats are two of the worst disease-carriers known! Because of faulty toilet accommodations, many jails possess an odor that sickens one upon entering. Few jails have screens, and the prisoners are at the mercy of flies and mosquitoes.

The remedies for the above named defects are obvious. Sunlight, fresh air, and proper sewerage must all be taken into consideration when building or renovating a jail. We must remember that a good percentage of the prisoners detained in jails are not condemned persons, but are persons awaiting trial. Under the constitution of the state and country, such persons are supposed to be innocent until convicted of guilt. Is it right, then, to endanger their health by confining them in a death-trap where

they may contract a disease which they may afterwards spread over the community.

While on this subject, let me say that in many jails there is no segregation of the prisoners. Juvenile petty offenders are thrown in with the hardened criminals, and the suspected man is placed with the convicted felon. Again, too little attention is paid to the segregation of the sexes. Men and women should have separate cells, as should the boy who is in for stealing and the man who is held for murder.

I have touched but lightly upon these problems, but I hope I have, in a measure, brought their needs home. Civic pride is a great aid to the healthfulness of a community, and if public buildings are not sanitary, they can be neither healthful nor beautiful. Cooperation as citizens in a clean-up of such buildings in a community is all that is needed. Progressive citizens desirous of better things for their children and their city should not blind themselves and, like the ostrich, think themselves safe if their eyes are hidden.

#### Disabilities Among Industrial Workers

In a report by Dr. Eugene Lyman Fisk, medical director of the Life Extension Institute, based on the examination of 10,000 industrial workers who submitted to periodic physical examinations, he finds that more than half of the disabilities discovered are preventable. Ten per cent of those examined were found to have slight physical defects requiring observation or hygienic guidance; 41 per cent had moderate physical impairments; 35 per cent had moderate defects requiring medical supervision or treatment and 5 per cent had serious physical defects urgently demanding immediate attention.

That illness is the cause of fatigue and not the effect, is the judgment of Dr. Fisk, who asserts that the length of the working day is a minor factor in the causation of industrial fatigue. It is the physiological conditions affecting the workers that result in undue fatigue rather than the period of work. "It is quite conceivable that if workers in an eight-hour plant and the workers in a ten-hour plant should have their physical deficiencies corrected to a reasonable extent there would be no difference whatever in the efficiency or rate of productivity in the two plants."

# Ohio Plan for Care of Crippled Children

By EDGAR F. ALLEN, PRESIDENT, NATIONAL SOCIETY FOR CRIPPLED CHILDREN, ELYRIA, OHIO

I HAVE been asked to give an outline of the work for crippled children as contemplated in what is known as the Ohio plan which is backed up by Ohio Rotarians.

First, the Ohio Society for Crippled Children is Rotary in the Tenth District in action. The management of the society is vested in a Board of Directors made up by the election or appointment of one person from each Rotary Club of the state. They, in turn, elect the Executive Committee and officers. To handle the entire state of Ohio, with an area of over forty thousand square miles, and a population of nearly 6,000,000, with 2,323 cities, towns and villages, in eighty-eight counties, in which there are altogether upwards of 12,000 crippled children, or about two to every thousand population, is the proposition for the Ohio Society for Crippled Children.

After a study of the work for many years, and the experience that we have gained through the caring for nearly one thousand children at the Gates Hospital for crippled children at Elyria, we have come to the conclusion that it is a district problem, and to handle effectively the work, and really reach the great army of crippled children scattered throughout the state in every village, town, and city, we must offer as many district centers with facilities for handling the crippled child as are pos-

*Contrary to the Iowa and Indiana plans of establishing one central state hospital to care for crippled children, the children to be committed from all parts of the state to it, is the Ohio plan of utilizing facilities at hand and taking them to the child.*

*The present plan of nine districts in the state in which hospital care is available for the treatment of deformed and helpless children was adopted by Ohio when it was found that 90 per cent of the children treated by a centralized state hospital came from a distance of only forty miles.*

sible. The Ohio plan reverses the old order of things in that we believe that the facilities must be brought, as near as possible, to the child, and not the child brought to the facilities. For this reason we have established in the state of Ohio nine different districts, which are as many as we can at the present time establish, and have in connection with these centers the proper facilities for the caring of the child.

We believe that there are two fundamental propositions which are the basis of our work. First, that the care of the child should be the duty of the state, and that through legislation, which has already been accomplished, we should throw upon the state its proper financial obligation in connection with the cure and care and education of the crippled child. The next fundamental proposition is to make available to private philanthropy through already established hospitals and their facilities the best medical, surgical and nursing care that they can give to the children who are taken in charge by the state.

The older idea of establishing one center in a state for the care of crippled children does not reach the problem, as from experience we find that 90 per cent of the children that have been cared for and treated in connection with one institution already established and in operation for the last seven years, and opened to all the state, come from within a

distance of forty miles. We believe that if we can establish ten or twelve working centers with total hospital facilities of from five hundred to one thousand beds, scattered throughout the state, with the provisions of Senate Bill 174 being cared for and functioning, that in time the crippled child will automatically be taken care of, which care will be paid for by the state, and will be worked through facilities established, and in the hands of private associations, which will, we believe, do away with red tape that surrounds institutions managed by the state. This plan, fully functioning, will eventually solve the problem, we think.

There are two pieces of legislation which have been backed and made possible by the Ohio Society for Crippled Children that are models, as we see it, in regard to the education and the cure of the crippled child. One is Senate Bill 174, already referred to, and the other is House Bill No. 200, which makes it necessary for Boards of Education to establish schools for crippled children in centers where there are more than seven or eight children found not receiving education at the general schools, the state allowing \$300 per year per child.

The next question to arise is how to make all these things possible, and that is where the Rotary Club comes in. It must see that in every county and city these different pieces of leg-

After an operation in the Gates hospital, Elyria, Robert was able to walk. From an economic burden he will become an asset to society.

This little girl threw away her crutches after an operation. Follow-up work will see that she has correct home treatment.

Children unbelievably deformed have been cured and their legs straightened and made strong by proper treatment which Ohio plans to extend to all its unfortunate children.

islation are made effective. It must be the policing agency throughout the state of Ohio, seeing that the work, even after legislation has been accomplished and facilities established, is properly done.

The next problem is the establishment of the centers and what constitutes a center. There are, as we see it, eight different points that should be complied with to make a center for the care of the crippled child. They are as follows:

(1) A Rotary Club with a vision of the work and a willingness to go through.

(2) Hospital facilities of twenty or more beds in a thoroughly organized hospital having a competent nursing force and proper equipment for all classes of work for crippled and deformed children.

(3) The establishment of a weekly clinic for new cases and also old cases where the patient can return to have casts, braces adjusted, x-rays, and examinations.

(4) An attending orthopedic surgeon with a consultant.

(5) A survey of the entire district as agreed upon and complete records made of all cases in the district.

(6) A system of follow-up work to be established in order that cases can have correct home treatment, and as far as humanly possible, children be made well.

(7) A school for the education of crippled children in the district and bedside teaching for children in hospitals.

(8) Classes for slightly deformed children, such as flat foot and curvature, where corrective treatment may be given.

All this work must be made to fit and coincide with what is being done by the state of Ohio and other agencies. For example, the public health nurse must play an important part, first, in finding and reporting crippled children; and second, by follow-up work for crippled children after the work at the hospital or convalescing home has been done. When a crippled child is found, the public health nurse should get all the history of the child and place it in the hands of the public health commissioner of the county or city, as the case may be. Also, she should report the case to the crippled children committee of the nearest Rotary Club. The findings of the nurse should then, by a public health commissioner, or by the Rotary Club, be given to the judge of the Juvenile Court. He, in turn, can commit the child to the care of the state through the State Department of Public Welfare. The state will then commit the child to such institution as is established for his care and treatment.

The second part that the public health nurse would be asked to do is in following up the child after it is discharged by the State Department of Public Welfare from such institution where it has been placed. This is very important and if carefully cared for can make the permanent cure of the child possible, whereas, in some cases if this follow-up work and care were not given, the child would not receive the full benefit of the work of the surgeon and the hospital, for in many cases a complete cure takes a very long time.

There must be a great deal of work given by the Rotary Club to the establishment of schools for crippled children. Referring to House Bill No. 200, we believe that schools will not be established in nearly as many communities as they should be, at least for a long while, unless Rotary Clubs in the different cities demand that this be done.

The Ohio Society for Crippled Children is a means to an end. It is the steering committee of the crippled children's work in Ohio. It is trying to make all these things, not only possible, but a reality. We have been very successful up to the present; we have brought to the attention of the people of Ohio this great need and its wonderful possibilities, and we are today working absolutely in harmony with the great departments

One of the 12,000 crippled children in the state for whom the Ohio district plan will facilitate treatment.

of the state who have the carrying out of the provisions of many different pieces of legislation. We are also working in harmony with all agencies that have been and are being established for the benefit of the crippled child, keeping in mind always that the duty of Ohio is not to any particular section but to all Ohio and that the crippled child in one county should have as good a chance as the crippled child in some other county.

If the present plans do work out in a large way, then the 12,000 crippled children that we have today will be taken care of, and not only that, but the 12,000 that will exist ten years from today will also be taken care of. That is our purpose, and that is the plan. What does this mean? It is said that the value of a life is economically between six and seven thousand dollars. So that if we are able to make possible the cure of three-quarters of the children there are now, and three-quarters of the children there will be in the next ten years that are crippled and deformed, and have turned those lives of dependency to lives of self-support, we shall have economically accomplished a value of hundreds of millions of dollars. What is even greater than the economic value is the humanitarian value which is beyond the words of man to express.

To sum up this movement, we find that we have already laid a foundation and made a start in a work, almost altogether neglected previous to our attempt, which reaches the values into millions and makes happy thousands. If this plan is successful in Ohio, we see no reason why the entire United States should not be worked out on the Ohio plan of taking facilities to the child and not the child to the facilities.

## A Cardiac Convalescent Home

A CONVALESCENT home for cardiacs, admitting to its confines men, women, and children of many nationalities and religions is the Burke Foundation, White Plains, N. Y. Founded by John Masterson Burke of New York City, in memory of his mother, the institution since its opening in April, 1915, has treated 28,008 patients, three thousand of whom have been suffering from organic heart disease. Ten thousand patients, representing seventy-five nations, were treated in the years 1919-21.

On the theory that the patients' health is dependent in great degree on normal social life, men and women and children are admitted to the institution and successfully convalesced together. Of the three hundred beds, eighty are reserved for cardiacs in need of rest and training to enable them to rehabilitate their energies to their full or handicapped capacities. The typical successful stay is from five to eight weeks.

Recreations and occupations involving physical exercises are encouraged at the Foundation and have been found to have a most salutary effect mentally and socially, according to Dr. Frederic Brush, medical director. Skiing, coasting, hiking, golf, croquet, and baseball are sports in which the convalescents participate. Dancing, taboo to many of the patients before coming to the Foundation, is considered one of the best recreations from the standpoint of mental as well as physical therapy. Two or three dances are given every week by the patients and a dancing class for cardiacs under eighteen years is held under the watchfulness of doctors and nurses. Dancing has stimulated the

psychoneurotic patients to a feeling of normality, of rising again out of prohibitions and above social invalidism. Contra and folk dancing are also practised.

Golf is the best adapted and most generally practised game at the Foundation. A short course laid close to the cottage steps is a popular feature. The slopes, varying from 2 per cent grade to steep bank of 20 per cent, induce much grade walking without

played, a six inning game with short runs and easy hitting. Field day programs with vigorous brief events in which the patients compete for prizes form a helpful factor. Contests for men include a fifty to seventy-five yard dash, throwing baseball, ten pound shot-put, ten pound hammer throw, discus, potato race, with similar but easier contests for the women and boys and girls. The natural play of children,—romping, wrestling, and

Occupational therapy is applied to 90 per cent of the patients. Outdoor work on the grounds, such as gardening and laying walks, is of high therapeutic value.

the consciousness of a set task. Holes are from ten to fifty yards in length, and the stroke is but "short approaching." Weekly prize tournaments with mixed sex and age groupings help maintain interest. Tennis, which amounts only to mild practice is played considerably by girls and young women.

Experience has shown that brief exercise is beneficial to the cardiac convalescent but that the danger comes in long and sustained exertion. Only a modified form of baseball is

tree-climbing,—has proved to be most beneficial to the juvenile patients.

Occupational therapy is being applied to almost 90 per cent of the patients from one to two hours daily. Shops for cement, carpentry, general repairs, basketry, and art supply work for many, while other patients keep up the grounds and buildings. Long-stayers work sometimes three to six hours daily for a modest wage. Outdoor work has been found to be especially beneficial to the cardiac convalescent. Women and girls find haying not too strenuous, while gardening furnishes suitable exercise for men. Aside from giving employment and testing the physical strength of the patient, occupational therapy has proved most valuable as a test of the individual's attitude toward the reparative effort and his life ahead.

The Burke Foundation is a convalescent home rather than a hospital, and admittance is made only when the patient has a reasonable chance of recovery. Cases are referred by various hospitals, physicians, and social agencies to the City House in New York, which acts as a clearing house and selects those best suited to the methods of rehabilitation practised at the Foundation. A thirty

"Short Golf" is a popular pastime with the cardiacs and is best adapted to their needs. Weekly tournaments with prizes keep up interest in the game.

Outdoor dancing, one of the most beneficial forms of therapy for heart patients practised at the Foundation.

passenger omnibus which makes the twenty-six mile trip in little over an hour carries the passengers with a minimum of exhaustion to the country institution.

Upon arrival at the Foundation, each patient is given a bared chest examination and graded as to the amount of exercise he may take. Marked cases of malnutrition are given extra milk and olive oil. A week later patients are examined medically and, as they show good progress, they are examined less frequently until the final conference for discharge.

Almost no drugs are used in the treatment of patients. Too much treatment and too many restrictions have made many of them border-psycho-pathic. The anti-drug régime helps to overcome their abnormal outlook. A low protein diet has been the rule and has proved satisfactory to the patients' condition of moderated physical activity and organic insufficiency.

When the patient has graduated through the various stages of light occupational therapy and sports, from subnormal work and play to increased play and occupation, and at the end of six or eight weeks is in a strengthened condition and ambitious to go back to work, special agencies place him in more healthful working conditions. Follow-up care is afforded through heart clinics and service departments.

Records kept of patients who have left the institution testify to the efficacy of the exercise method of therapy. In fact, those making the most progress during treatment are those exercising most, "the triers," while the slow gains and partial failures occur in others who, through fear or obstinacy, maintain an attitude of physical inertia with its usual border-neurasthenia. Of sixty-nine leaving

the Foundation during 1919-20 who registered with the Bureau for Employment of the Handicapped in New York City, sixty-four were newly and well placed, one was returned to his former job, another to his western home, one was too young to obtain working papers, while two were considered too ill for placement when they came to make application. At the

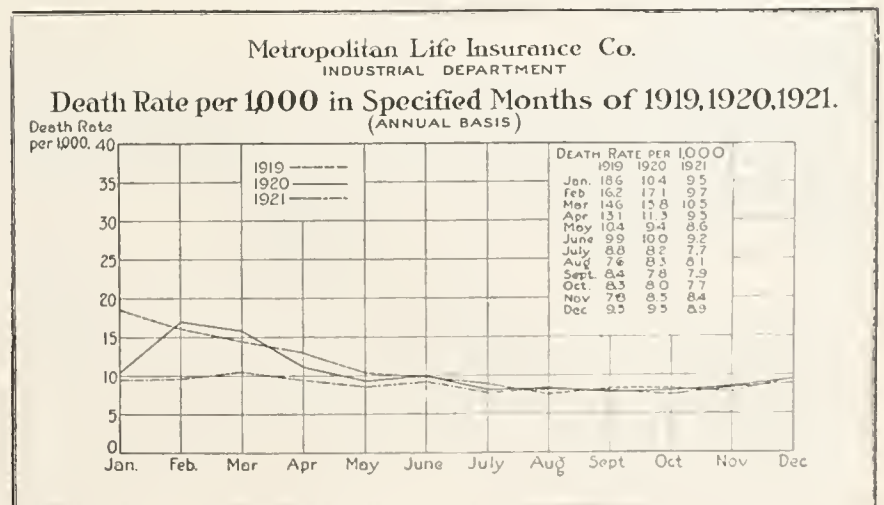

end of the year fifty-nine held their positions, the majority being in improved health and contentment, ten had been back in hospitals with heart attacks for short periods, fourteen others had heart treatments as out-patients, and one elderly man had died suddenly while at clerical work. Fifty-five were still cooperative with their cardiac clinics. This group was below the average of discharged patients in physical and economic fitness, some of them not having previously worked for months or years.

While the work of heart convalescence has grown in the last six years from the almost negligible to the near ideal, the prevention of diseased heart strain lags. This prevention can be best accomplished only through country care which affords rest and diminishes stress. The open spaces and distances inducing walking, play, work, and mental exercise make the rural environment the most beneficial in the reconstructive convalescence of heart disease.

## Mortality Rates Reduced

PERIODIC health examinations, wholly voluntary in nature, carried over a six-year period by the Metropolitan Life Insurance Company as an experiment in life extension, have recently been credited with a reduction in mortality among this group to 53 per cent of that expected. The result is striking and suggests its extension to limit the needless loss of life from certain definite diseases. Cancer, Bright's disease, cardiac conditions, and tuberculosis together re-

duce the span of life by about eight and one-half years for white people, all of them being more or less subject to control, especially in the younger age groups. The trend of public health is indicated by deaths from week to week and it is proposed to pool the data of the several insurance companies, tabulate them, and make reports in aggregate to such governmental agencies as need this information for use in fighting the battle for better national health.

That better health and improved life expectancy are not merely visionary is evidenced from the steadily increasing rise in rates above those expected shown in this chart.

## The Play of a Nation

THE imperative need of play by both children and grown-ups in this modern civilized day and the recreational value of different sports and pastimes are set forth by Dr. G. T. W. Patrick in a recent issue of the *Scientific Monthly*.

Americans live tensely and under high pressure. In order to avoid mental and physical breakdown recreation must be truly so and not mere entertainment; it must relieve those brain centers which are overtaxed in our daily life of work and worry; it must be essentially different from our work; it must have the elements of rivalry, competition, and contest; it must provide for self-expression; it must be preferably out of doors.

The popularity of football, baseball, and outdoor life is ascribed by Dr. Patrick to the fact that they exercise the older brain patterns and represent a reversion to natural outdoor life. "Applying our tests to these forms of play, it becomes clear at once that golf, tennis, baseball, football and basketball stand out pre-eminently as real recreative sports. From the psychologist's point of view, golf may be cited as the perfect ideal sport. It has all the needed recreational elements. It has a restorative power excelling all therapeutic arts. It represents a reversion to the natural outdoor life. We range over hills in the open, using the muscles of the legs, arms, and trunk. We carry a club and strike viciously at a ball. We search for the ball in the grass as our ancestors searched for their arrows. There is a goal and

the spirit of rivalry and a chance for self-expression. The nerve currents course through ancient channels. We return to our work refreshed and rejuvenated. Golf, to be sure, requires fine adjustments of the eye and hand at the moment of striking but there is no continuous strain upon them and skill of this kind is a proper element in play. It is unfortunate that the opportunities for golf are now limited to the few. Nothing better could happen to our nation than a wide extension to our people of the opportunities to play golf.

"As regards tennis much the same may be said. Though lacking some of the distinctive psychological elements of perfect sport possessed by golf, it is still a very excellent and healthful form of recreation. Opportunities for it should be widely extended.

"Baseball and football have certain peculiar qualities which rank them as high or possibly even higher than golf. Being more strenuous, they are better suited to the young males, while golf and tennis may be played by all. We see at once that football meets all the conditions which we have outlined as marks of good sport. There is running, kicking, dodging, tackling, pursuit and capture. There are also the opposing groups, as in battle, and the rough rude shock of personal collision. All these ancient responses offer complete relaxation and release from the proper and pent up inhibitory life of our modern world. They arouse latent, deep-seated instincts and impulses, allow us to revel for an hour in these ancient memories

and restore us to our work refreshed and purified. It is the grip upon us of that which is racially old which explains the immense throngs which gather at the football games. Seventy or even a hundred thousand spectators have been reported at some of the great games.

"The racial elements in baseball are not quite so old but are sufficient to permit the *catharsis* element in rare degree. Striking and throwing are dear to every boy, and these ancient responses, the ancestral conditions of race survival, are dominant in baseball, while the running and catching, and the opposition of the teams, and the reward of skill and of strength and quick decision add to the real recreational value of the game. The recent extension of non-professional baseball and football among school boys is a contribution to social welfare. Here again, however, the application of the statistical method awakens our concern. For if baseball is fitted to all young men from the ages of fourteen to thirty, actual regular participation in it will be found to be limited to relatively few. It should be extended to a larger number.

"But professional baseball as a national sport presents a different problem. Here the 'players' are not playing but working. The game is a profession, a strife for glory and for money. The recreational features are now transferred to the spectators. To what extent is baseball of recreational value to the fans? They usually ride out to the ball park in auto or street car, sit on the bleachers during the game and return as they go. Nevertheless the game has considerable recreational value for the spectator. The galling social checks and inhibitions of the daily grind are thrown off for a time. Free expression is given to one's feelings and enthusiasms. There is a mental participation in the game and no doubt usually a considerable degree of rest and relaxation is gained. But it does not permit of self-expression and is far from an ideal form of play and at the best the number enjoying it is relatively small. Basketball, though lacking in some of the distinctive recreational elements of baseball and football, is nevertheless of the greatest value as a sport and stands high in our list.

"Hunting and fishing, swimming and camping constitute a group of sports which rank high in the list of valuable recreations. They represent a return to primitive life and involve

Rivalry, competition, and contest, ancient forms of self-expression, are present in relay racing, thereby making it a truly recreational sport.

Basketball, especially when played out of doors, stands high in the list of healthful games.

only racially old and familiar brain patterns. They are out-of-door sports, using the fundamental muscles of the arms and legs and completely releasing the strain upon the eye and hand and nervous system. Hunting with the camera, recommended by humane societies, is well enough, but the camera is not a substitute for the gun in recreational value. When we consider the horrors of the late war and remember that if the nervous tension of a people gets too high it may overflow in an actual orgy of human bloodshed, the 'cruelty' of hunting and fishing seems less serious, especially if they act as a release of the nervous tension increased by our high pressure modern life."

But though the recreations mentioned in the foregoing paragraphs are truly recreations, they are available to comparatively few Americans, while the automobile, the dance, and the movies are accessible to millions of our population. With eight million automobiles in the United States carrying as passengers men, women, and children, motoring is a popular pastime. Judged by the criteria of good play, motoring takes man out of doors; it satisfies his roaming instinct and his desire for speed. For old men, for shut-in women, and for those who work on their feet, it furnishes rest, relaxation, and fresh air. But for the average man and woman and especially for the child, the automobile is disastrous. Modern life has made man a sitting, lounging, reading, studying, thinking being where heretofore for hundreds of thousands of years he lived on his feet and made his living by means of his legs. The

extensive use of the automobile deprives many of the little walking they would otherwise do.

Though the movies with an attendance of twenty million men, women, and children every day is perhaps the most widespread amusement, judged from the standards of a real recreation, it ranks very low. The physical conditions in moving picture houses are of the worst. Children are confined to one seat, their attention is wrapt, and they remain in a rigid position for hours. The tax on the eyes, the most overworked sense organ in modern days, is also great in moving pictures. From an emotional viewpoint the motion pictures are harmful for they arouse a great flood of feeling which leads to no action. Their moral and social influence is often degrading.

Dancing, which ranks as one of the great amusements in America, is from a physiological point of view recreational. It is an instinctive form of enjoyment; it relieves completely the strain upon the eye and finger muscles, involving only the ear and the larger muscles of the trunk and legs; the rhythmical movements are ancient, easy, and natural. It follows the older brain patterns, thus resting the more highly specialized centers, and it gives an opportunity for self-expression. The sex factor, the fact that it is indoors, is largely a night pastime, and has associated

Older brain patterns are involved in running and jumping, thus giving the newer and more highly specialized centers a rest.

with its other unhealthful conditions, lessen the recreational value of dancing.

The solution of our social problems is largely a matter of healthful and harmonizing recreations, Dr. Patrick believes. These could be provided through the greater accessibility of outdoor sports and a revision of the school program in the direction of the English system in which sports and play are an integral part of the curriculum.

## Race Stock and Vitality

An interesting analysis of changes in population composition is obtained in California during the period of 1910-1920. The population increase of 44.1 per cent for the intercensal period indicated a growth in all major race stocks except the Chinese which decreased 20.5 per cent. The white race showed an increase of 44.4 per cent, the negro 79.1 per cent, and Japanese 74.0 per cent. Further analysis reveals the fact that 65 per cent of the population increase among the Japanese is due to excess of births over deaths—a proportion much larger than that found in any other race.

The Monthly Bulletin of the California State Board of Health states that, whereas, the Japanese composed only 2.1 per cent of the total population, they were credited with 7.4 per cent of all births and only 2.1 per cent of all the deaths. Comparison of the infant deaths and stillbirths indicate

low rates among Chinese and Japanese; the whites, negroes and Indians appearing unfavorably. The Chinese death rate exceeds its birth rate as the population is older and in time the operation of the exclusion law will result in higher death rate.

No race in the state compares with the Japanese in rate of reproduction and vitality. The 1920 birth rate was 67.6 per 1,000, a record without parallel in modern vital statistics. Coupled with this is an infant mortality rate of 68 per 1,000, 7 points lower than the white rate, and a stillbirth rate of 20.9, almost 12 points lower than the whites. In 1920 alone the Japanese increased their population 5.4 per cent by reproduction while the whites increased only one-tenth as fast. Negroes and Indians have unfavorable characteristics in their vital statistics with low birth rates, high rates for deaths, stillbirths and infant mortality.

## Begin Right—Live Out of Doors

MUCH is written about the tragedies of the grown-ups of one-track minds who did not have the proper warning and the proper training in youth to develop a few parallel tracks. The importance of starting young, and of training the individual to give intelligent direction to his recreational activities, as well as his more serious tasks, is constantly stressed. One writer said, recently: "When young folks are taught the worth and ways of recreation, they are taking out an insurance policy against nervous disorders; and in middle age, when they come to collect, they will find themselves reimbursed a hundred-fold."

Not along physical lines alone, but mental—even moral arbiters are unanimous in pleading for early training in order to reap the full benefits of the opportunities which come to those who are properly trained, with the passing of years.

Why not, then, begin aright? Why bemoan and regret the lost advantages of youth, while refusing to open the eyes and minds of the somnambulant youth of today? In a few short years these children will stand in your places, and if you have done nothing to train them properly, they will be just where you are, lamenting their lost opportunities, and, as like as not, doing nothing to advance the progress of their offspring, in turn, along these latter-day concepts of right living and thinking.

Why is it that hundreds of parents read editorials, attend lectures, hear on all sides of the value of proper instruction for their children, who fully agree with all they hear or read, who think such projects are splendid, but who actually do not one thing to enforce such training upon their children? It is because they do not think, in a majority of cases. They imbibe such teachings in a detached way, never for an instant feeling that the message is meant directly for them. Let the school teacher, the next-door neighbor, let the other fellow assume the responsibility, but don't bother the average parent with the necessary study which such training entails.

And so the children lose much in life because they are untrained along recreational activities. They do acquire a general knowledge of athletics in their school curriculum, but the major portion of such training is, necessarily, confined to the indoors, and then, to short periods of time.

The proper kind of recreation is that spent in the out-of-doors, out in the fresh air, where clean, wholesome pursuits make for strong, vigorous bodies. Because school hours confine children to the schoolhouse ten months of the year, the only period in which training for correct recreational activities can be given unrestrainedly is the summer vacation period. Naturally, this must be done with organized groups of youngsters, to achieve results. Oftentimes, especially in the larger cities, campgrounds are not readily accessible, and much of the beauty and joy of learning how to live in the open is missed.

The summer camp is the logical

place for introducing the worth and ways of recreation. There are many such, worthy, reliable camps, the camp-fire camps for girls, the increasingly large numbers of boys' camps, so located as to be accessible from all parts of the country, and the scope of the instruction offers unlimited opportunities to all who partake of their programs.

Why do not parents of growing boys and girls of today study the summer camp ideas and ideals? Why don't they investigate and find out for themselves what these camps will do for their children, in building better health, better morals, in teaching democracy and better citizenship? Why not take out insurance in favor of your child's future? Join hands with Science for the care of your child.

## Los Angeles Outdoor Relief

THE Outdoor Relief Division of the Los Angeles County Charities has just issued a report on its activities at the close of a five year period during which time the many ramifications of relief and rehabilitation work have been brought together, fully coordinated and the work systematized so that now it operates, without overlapping in interest or effort, as a single unit.

The giving and withholding of relief intelligently is no mean achievement, and public aid without pauperization is the objective in really scientific reclamation work.

Organized charity encourages thrift

and infuses new life into the discouraged. It compels a man to recognize that within himself, no matter how dormant it may lie, the spark of independence and self-respect still exists. It requires but the kindly word, the helping hand and simple faith in a fellow man to rejuvenate a broken life and bring it within the pale of recognized citizenship. The mere offering of food may appease hunger and satisfy this need for a time, but sympathetic service, given with this other essential, is often more helpful than the food itself.

A large majority of applicants are broken on the wheel of life either

People who are old, weakened by illness, or handicapped by some permanent disability find intelligent direction which enables them to take up new means of earning a necessary wage. There seem to be no age limits to acquiring new interests.

through sickness or infirmity, and were it not for these misfortunes, they would not become seekers of charity. Young mothers, with little broods clinging to their skirts, find it physically impossible to meet the demands made upon them now that the breadwinner has been taken by death, and they are forced, through stern necessity, to ask aid. Deserted mothers, too, come under this category and hundreds of babies, robbed of parental love and care by death, domestic differences and other causes, form another contingent that are entitled to preservation and protection from the vicious circle of destitution.

### Cooperating Agencies

Splendid cooperations has been extended by the Jewish Aid Society, Bureau of Catholic Charities, City Nursing Division, various clinics of the City, County Public Welfare Commission, City Social Service, Children's Hospital, the Elks, particularly Glendale Lodge, the Masons and various other private organizations.

Occasional meetings with the various groups of social workers and philanthropic bodies, to whom we have at all times taken pains to explain the laws and principles under which the County Outdoor Relief is operated, and by making our method of operation clearly understood, we have removed many prejudices which existed heretofore.

The confidential exchange of the results of investigation has grown to be a very important factor. Social workers are turning more and more to this Exchange, as they realize that the best case work cannot be done

The handicapped men themselves become vitally interested in the work and find rejuvenation through creative effort.

without the aid of this branch of the department. Unless agencies pull together and work with one definite end in view, each counters the labors of the others. Team work has been found to be the keynote.

The Confidential Exchange aids in many ways. It saves duplication of labor by giving to each agency the knowledge of the other. It aids in distinguishing the worthy from the unworthy and in giving relief wisely. It assures better diagnosis and treatment, promotes better understanding between agencies, and it systematizes the work by keeping an accurate record of all cases.

The Exchange consists of a card index of all cases known to the organization. Each card contains identifying information of the family or

individual, such as names, ages, occupations and addresses. There is also a street card index. These cards give the address and name of the family, and are filed alphabetically according to the name of the street. By means of this card index we can often locate a family when we fail to do so in the general index, due perhaps to difference in spelling. The Exchange also furnishes files in which the closed or "dead" cases are kept.

Social agencies either telephone or send in printed slips of inquiry concerning certain cases. The person in charge of the Exchange looks up the case and notifies the inquirer of other agencies in the city who are interested in that particular case. With this knowledge, the workers can get together and decide on some plan of follow-up work.

At the present time we have approximately 30,000 cards. The number has increased nearly 3,000 in the fiscal year 1919-20. Eighteen agencies in the city are making use of the Exchange, both in making inquiries and in reporting cases.

During the past fiscal year the County has handled 678 families, which represent 1819 children, who have been eligible for assistance from the State. For these families \$186,517.36 has been expended. Of this amount approximately \$151,439.68 will be refunded by the state. The balance, \$35,077.68 represents the amount supplemented by the County to that allowed by the State.

Many children are receiving County Aid, who are not entitled to State Aid, for the reason that probably they have not been in the County long enough to be considered, time

New interests make new men of human derelicts.

of required residence being two years prior to date of application. During the fiscal year the County has taken care of in this way 362 children, distributed in homes and institutions, some for various and legitimate reasons needing temporary care outside of their own homes.

The salvage department will soon occupy a remodeled building which will be devoted to reclaiming waste materials. At the present time there are in operation the following departments: Sewing Department; Shoe Department; Tailoring and Pressing Department; Paper Department; Millinery; Laundry and Ironing; Cabinet and Furniture Repairing; and Paint and Varnishing Department.

Each of the departments is to be operated as a training school, free of charge, where dependents may be taught a craft, and when sufficiently skilled will be given employment in proper factories, thereby becoming independent, thus renewing their faith in themselves, strengthening their character and removing them from County support. These training schools are, however, not confined to charity dependents. The general public is permitted to join in, and through their efforts the many articles of salvage are reclaimed and rebuilt, and when finished are distributed for charity, saving just so much to the taxpayers of Los Angeles County.

#### Industrial Extension Work

Most satisfactory results have been obtained in the division for the handicapped individuals, who have been brought to our attention. It is indeed very encouraging the way they have grasped and mastered various lines of work.

Through this agency ninety-nine persons have received instruction in seven different crafts, such as chair caning, weaving, jewelry making, the manufacture of reed furniture, etc. Eighty-two positions have been secured at salaries ranging from ten dollars a month to as high as one hundred dollars a week. Five hundred garments have been remodeled and patched, sweaters have been knitted and quilts made. Fourteen firms and six prominent individuals have cooperated in securing positions for clients. One blind man learned basketry sufficiently to go into business for himself, and is at the present time supplying the local trade. Another blind man has accepted a position in a reed furniture factory. One lady, who came to the Handicapped Bureau on crutches,

feeling discouraged and practically down and out, was encouraged to do something for others as well as herself, and she has been engaged by one of the moving picture concerns in a part requiring crutches, at a salary of one hundred dollars a week.

Fifty or more books which have been given to the organization are passed out among the old people to read. Ten men have been trained for elevator operators and placed in positions. Fifty per cent of positions filled have been permanent. Twenty-one blind men have received instruction in various lines. Three deaf mutes are receiving training in handicraft.

The past year has been filled with problems, which have all been met through the resources and cooperation of the entire Outdoor Relief Division. In every way the work has been held up to the highest and best ideals, and an avenue opened up through which many prominent citizens without publicity to themselves have been able to assist in real constructive work for their less fortunate brothers and sisters. As proof that the handicapped people themselves are vitally interested in the work, they are waiting for the doors to open in the morning, and must be reminded several times later in the day that it is time for them to quit. Handicraft for the handicapped is solving the problem, proving that blindness is only a handicap.

Much is accomplished in reclamation work of any character, with the change in attitude which comes from hopefulness through self-help. When the means of rising above the handicapping condition are afforded, there is little trouble in evoking new energy and new capabilities. That the work is sound and the benefits permanent are fully exemplified in the cases reported.

#### Diphtheria Cost New York City \$581,825

Dr. William H. Park, Director of Laboratories of the Department of Health, New York City, recently submitted a report which showed that the average cost of a case of diphtheria is from fifty dollars in a contagious disease hospital to more than one hundred dollars when the patient is cared for at home. The cost of the cheapest funeral Dr. Park set down as seventy-five dollars. During the first six months of 1921 there were 10,722 cases of diphtheria reported in New York City, and 611 died. Ac-

ording to the estimate, the 10,722 cases cost \$536,000 and the cost of the 611 funerals was \$45,826, making the total cost resulting from the disease during the six months \$581,825.

"The remedy against all these losses," the report said, "is the giving of the Schick test to ascertain the susceptibility of an individual and the elimination of susceptibility by the protective treatment. The cost of protecting one child is twenty-five cents. The cost of protecting every one of the million school children would be \$250,000. We were enabled to give the Schick test to more than one hundred thousand in 1921 and immunized forty-five thousand children."

#### Schools for Crippled Children

An act authorizing and empowering any school district in the State of Minnesota to provide for, establish, conduct and maintain schools for crippled children in such districts and appropriating money therefor was passed by the 1921 legislature. The teachers and nurses appointed to these schools are to be under the direction of the Commissioner of Education, and in addition to the usual qualifications, are to possess such special training as he may require. The sum of two hundred dollars for each child is to be paid out of the State school fund to the districts maintaining such schools.

#### Zinc Oxid Dermatitis

"Oxid-pox" due to the clogging of the sebaceous glands with zinc oxid and to infection has been found by J. A. Turner among workers in a zinc oxid manufacturing plant. The results of his investigation have been published in U. S. Public Health Reports, Vol. 36, No. 44, Page 2727. The zinc oxid body debris, and bacteria are forced into the sebaceous glands, distending them, aided by free perspiration and the rubbing together of two body surfaces. The dermatitis is characterized by a papular-pustular eruption in the pubic region, in the axilla, and on the inner surface of the arms.

The disease occurs most frequently during the summer months and its occurrence depends largely on the personal cleanliness of the worker, as no trouble is experienced if daily baths are taken. Special clothes of close weave, fitting snugly at neckband, wristband and ankles are recommended as a means of preventing contact of the oxid with the skin.

# A strain on the feet is a tax on the health!

**P**HYSICIANS know that a constant strain on the feet results in injury to the nervous system, pains in the back and limbs, and often in a noticeable decline in bodily vigor.

In fact, it is impossible to be normally healthy when the feet are not kept free of strain. Even a slight strain—a discomfort—if allowed to continue causes damage.

The cause of nearly all cases of strain on the feet is incorrect shoes. The foot is designed solely for the purpose of bearing the weight of the body—being, really a framework similar to an arch bridge—and like a mechanical structure, a bridge or a building, there is sure to be strain unless an adequate and proper foundation is provided for it to rest on.

Nature intended us to go barefooted. This gave support at three weight contact points on the bottom of the foot, the heel, the outer arch and the ball. When people went barefooted they never knew foot strain or discomfort, and under such natural living conditions their general health was usually good.

Civilization demanded heels, and shoes were developed with heels—but in at-

taching the heel and raising the walking base of the foot, the outer arch was left unsupported. In the ordinary shoe the outer arch—one of the three weight contact points created by Nature—is left to sag down; to cause a strain on the foot; to injure the bodily health.

And so today we find that practically 90% of all women are suffering from foot strain, and are affected seriously by this discomfort, simply because they insist on having their feet well groomed and do not know they can secure both style and comfort at the same time.

But the Arch Preserver Shoe, because of a concealed built-in arch bridge, improved lasts, and a correct\* system of fitting from heel to ball, a system originated by us and based on the measurements from which lasts are made, gives all of the advantages of going "barefooted"—and yet allows the wearing of fashionable heels.

The Arch Preserver Shoe satisfies both Nature and Fashion. It is in good style; it is sensible; it promotes general health; increases business efficiency. The trade mark below is on the sole and lining of every Genuine Arch Preserver Shoe. (There is a special model for nurses.)

*The Arch Preserver Shoe is manufactured for women and misses, in all styles, widths A.A.A. to E. Sold by 2,000 dealers. Ask for interesting booklet No. 53 regarding foot health and comfort.*

THE SELBY SHOE COMPANY

43 Gallia Street

PORTSMOUTH, OHIO

Nature plans that the foot rest on heel, ball and the outside arch.

Civilization demands that the heel and arch be raised.

The Arch Preserver Shoe and its shank satisfy both Nature and Civilization.

## THE ARCH PRESERVER SHOE

## Influenza Commission Report

A "progress report" of the Influenza Commission of the Metropolitan Life Insurance Company organized in 1919 appears in the *Statistical Bulletin* for December. Some of the more significant findings follow:

(1) One attack of influenza does not confer permanent immunity and it is probable the immunity disappears within a year.

(2) The vaccines tried do not protect against influenza.

(3) The Pfeiffer bacillus is generally found in cases of influenza but is a secondary invader and not the true cause.

(4) There are many different strains of influenza bacilli which are harbored by many healthy carriers.

(5) The discovery of the identity of the microorganism causing influenza is one of the most pressing problems facing the Commission.

(6) Special studies are being conducted in Boston, New York and Baltimore of methods for the treatment and prevention of pneumonia, the most frequent cause of death in influenza cases.

## Death Rates a Blot on Civilization

The following resolutions were adopted at the Tenth Annual Congress of the National Safety Council which was held at the Massachusetts State House in Boston recently.

Whereas the 80,000 accidental deaths and millions of injuries occurring each year on the streets, in our industries, in homes, and elsewhere more than twice the number of all American casualties in the great war are a blot on our civilization; and

Whereas, National experience has demonstrated that 75 per cent of industrial accidents are preventable; experimental campaigns in seven cities have resulted in the reduction of public accidents by 25 to 40 per cent and further efforts will undoubtedly result in even greater progress; and

Whereas, The direct economic cost of accidents in industry alone exceeds one billion dollars annually, and greater indirect losses are caused by the curtailment of production and lowering of morale. Therefore, be it resolved that the National Safety Council at its Tenth Annual Congress in Boston assemble advocates:

(1) The safeguarding of all dangerous machinery and places according to methods that have been found practical and effective.

(2) The re-designing and reconstruction of factory equipment when necessary and the improvement of dangerous processes for the purpose of removing the accident hazards, and at the same time increasing industrial efficiency and lowering cost:

(3) The education of all workmen and their supervisors in safe methods and habits of work:

(4) The safety education of all school children, as well as students of our colleges and universities, both for their own safety and to stimulate interest in the conservation of life and a better citizenry; and

(5) The mobilization of all com-

munity forces, including city and state at safety councils for intensive and permanent campaigns against accidents of all types.

## Detroit's Experimental Nursery School

An experimental nursery school is soon to be established in Detroit, Michigan, by the Merrill Palmer School, in cooperation with the board of education. Girls selected from the public schools will be trained in the care of children of preschool age, taken from homes where there are no mothers to look after them.

## A Job for Business Men

THE strain on the human mechanism has been so greatly increased by modern commercial and industrial conditions that the business world must insist upon the schools developing physically as well as mentally fit, the *New York Times* reports from William Mathew Lewis, Chief of the Education Service of the Civic Development Department of the Chamber of Commerce of the United States. Since efficiency is founded upon good health, he believes that the business men of the country in future will investigate for themselves conditions in schools where children may be subjected to overcrowding, poor lighting, ventilating and heating, and insist that proper accommodations be provided.

"The business world," says Mr. Lewis, "has much at stake in the matter of building in our schools citizenry which is physically fit. The times demand men and women who can stand the strain of the most trying commercial and industrial conditions the world has known. Health is the basis of efficiency. With specialized production and with the use of the telephone and other time-saving devices, physical exercise in connection with the day's work is greatly restricted, and as a result there is a constantly increasing number who break down in what should be the prime of their productive lives."

Proper medical inspection and physical training in our schools must be the answer to this condition. He who starts in the economic struggle without the proper physical equipment is limited in his choice of life work and in his ability to reach the top. Our future workers are not being given a fair start.

Out of 100,000 pupils in New York public schools alone who have to repeat their work yearly, 50,000 have

defective eyesight. In a school in Detroit, Mich., 600 children were graded by mental tests. Of the 100 with the highest rating, 44 were without any physical defects. Of the 100 with the lowest rating, only 17 did not have such defects. In Omaha during the last school year 22,249 school children were examined. The total number of physical defects found was 18,882. Through the knowledge thus obtained, 46 per cent of those examined were relieved of the defects and started on the way to successful life. Statistics show that pupils with good teeth make better grades in school than those with poor teeth. Likewise they do better work when they get into business.

During 1917-18 the Health Department of the City of New York estimated that about 20 per cent of the children in the public schools were suffering from malnutrition. Of 59,000 children examined in Detroit recently, 19 per cent were ten pounds or more underweight and nearly 7 per cent were 15 per cent or more underweight. Will such conditions add to our future industrial and commercial efficiency? More than fifty years ago, Herbert Spencer pointed out the fact that healthy training was the first consideration in education. Centuries ago the Greek teachers stressed physical development and produced the highest type of civilization the world had known.

We have been slow to learn the lesson they taught. The time has come when the business men must find out by personal investigation whether the children of their communities are getting a decent start in life. They must see for themselves whether or not children are cooped up in buildings where wrong lighting ruins the eyes, wrong seating twists the backs and poor sanitation promotes disease. The facilities and leadership in the teaching of health and the development of strong bodies must likewise be investigated.

For a period of years over 50 per cent of the deaths among Michigan school teachers between the ages of twenty-five and thirty-four have been from tuberculosis.

## Examine Your Patients' Feet for Structural Weaknesses

Weak or fallen arches or flatfoot are often the direct cause of many bodily complaints such as fatigue, nervousness, pain in legs, sciatica, painful heel, cramped toes and rheumatic symptoms. Mechanical treatment is indicated along with properly fitted shoes.

### *Dr. Scholl's* *Corrective Foot Appliances*

are especially designed on anatomical and approved orthopedic principles to relieve the cause of the ligamentous strain and correct the abnormal posture. Worn inside the shoes, are comfortable to wear and easily adjustable to meet all conditions as presented to the physician.

### Sold at Shoe Stores

Better shoe stores in every locality carry the full line of Dr. Scholl's Corrective Foot Appliances and have also been instructed in how to properly fit them. Write us for the name and address of the dealer

nearest you, Doctor, and let us tell you more about mechanical orthopedics of the foot, which subject is attracting so much attention from the medical profession at this time.

## Relation of Lung Activity and Malnutrition

Dr. Royal S. Copeland, Health Commissioner of New York City, is reported as favoring measures to build up frail children through fresh air and proper breathing exercises. In many instances lack of lung capacity and lung activity rather than poverty, is ascribed by him as being responsible for the malnutrition of the 200,000 school children in New York City. In a letter to the superintendent of schools, Dr. Copeland asserts, "It is my opinion that every school child should have daily setting-up exercises, given with particular thought to chest and lung development. At regular times, morning and afternoon, deep breathing, together with simple but effective movements of the limbs and body, should be practiced by every pupil and teacher."

## Health Service Prescribes for a Sick Stream

An intensive study of stream pollution with special regard to the establishment of a general plan by which any polluted stream in the United States might be purified at a minimum expense has recently been begun by the United States Public Health Service.

As is well known a polluted stream tends to purify itself, but its power in this direction depends on the amount and character of the original pollution, on volume and speed of the current, and on the extent to which new pollution is added along its course.

The Service has selected for study the Chicago Main Drainage Channel and the Illinois River, which empties into the Mississippi, chiefly because all the primary pollution of this stream originates in Chicago and is accurately ascertainable, both as to amount and character. Analyses taken along the course of the canal and river will determine the degree and nature of the changes that take place in it. Where new pollution is added, its amount and character must be ascertained; and its effect on the old pollution learned. This last is important, for it is quite possible that sundry industrial wastes might neutralize each other or might destroy certain types of organic pollution.

Similar work was done on the Ohio River from 1914 to 1917; and the present study is to check the results obtained there.

The final object is to establish fundamental quantitative relationships be-

tween bacteriological and chemical pollution of a stream on the one hand and basic principles, such as population, industrial wastes, stream flow, and prevailing temperature, on the other. These relationships, once established, will guide the sanitary engineers as "streamdoctors" in prescribing for a sick stream the sort of tonic required to restore it to health, and thereby make it available for human consumption or industrial purposes or both, as may be desired.

The work in Illinois is in immediate charge of J. K. Hoskins, Associate Sanitary Engineer of the U. S. Public Health Service, and is under the general supervision of Surgeon W. H. Frost.

## Three Agencies Unite in a Five-Year Program

An interesting experiment about to be undertaken in the city of New York is outlined in a recent issue of *Better Times*. The Commonwealth Fund has undertaken to finance for a period of five years a broad and comprehensive experiment in methods of preventing delinquency. An appropriation of \$165,950 has been made for the first year. The National Committee for Mental Hygiene, the Public Education Association, and the New York School for Social Work will each conduct correlated activities as a part of the program.

The National Committee for Mental Hygiene will, through its new division on the prevention of delinquency, maintain a psychiatric field service for juvenile courts in communities which wish to organize psychiatric clinics or to conduct experiments in the working of such clinics. Only communities employing visiting teachers may avail themselves of this service.

The Public Education Association will continue its special classes for abnormal children and will place visiting teachers in the schools of ten, and later twenty communities.

The New York School of Social Work will conduct a psychiatric clinic to be known as the Bureau of Children's Guidance, which will undertake the examination and treatment of children who present behavior problems. It will be located at 8 West Forty-eighth Street, and will be under the direction of Dr. Bernard Glueck. The staff will include an assistant psychiatrist, a psychologist, social workers and assistants. "The number of children handled by the Bureau," said Porter R. Lee, director

of the School of Social Work, "will be limited to those who can be effectively treated with the facilities available. Throughout the work the importance of thorough treatment will be stressed. It is hoped that during the five-year period definite progress may be made towards a better understanding of the foundations of behavior and the possibilities of dealing with behavior difficulties before they become seriously crystallized."

## Lakeman is New Secretary of N. Y. Health Board

Mr. Curtis E. Lakeman has been appointed Secretary of the New York State Department of Health to succeed Dr. John A. Smith, resigned. Mr. Lakeman was formerly Secretary of the New York State Water Supply Commission, and later served as Secretary to Dr. Ernst J. Lederle during the latter's second term as Commissioner of the New York City Department of Health. Since 1913 he has been connected with the American Society for the Control of Cancer, of which he was Executive Secretary until released for service with the American Red Cross during the war. He has recently returned from two years' work on the staff of the League of Red Cross Societies in Geneva, Switzerland, and as Assistant to the American Red Cross Commissioner to Europe in Paris. Mr. Lakeman is a graduate of Harvard University, class of 1904, and has been for several years a resident of Larchmont, Westchester County.

## Children Interested in Principles of Nutrition

Under the direction of Prof. C. E. Turner of the Massachusetts Institute of Technology, school children of Malden, Mass., are learning of healthful foods by visual methods. Children become interested in the kind of food they eat when the food constituents are personified, says Dr. Turner. When eggs and milk are known as the twin fairies of "Growth Material" and "Repair Material," when energy-making cereals are visualized by the Brownie "Pep," when regulator foods such as vegetables and fruits are "Mr. Policeman" and mineral foods in carrots and apples as the "Iron Knight," the teaching as well as the application is simple. A full-time specially trained teacher has been appointed for the Malden schools this year and four hundred children from 9 to 14 years are being taught practical hygiene.

## How the Right Shoes Increased Her Sales

*A true story with a lesson for all men and women*

"MISS GREEN, you and eight other girls out of seven hundred have shown increased sales during the last three months. All the others show losses. Why have you been able to increase your sales?"

"Who are the eight girls?" asked the young woman.

The president of the store read the names. The girl seemed happy to answer:

"Shoes—Cantilever Shoes. I got them first. Later I took each of those girls, in turn, to the Cantilever Shop. In Cantilevers, you see, our minds are off our feet. The business gets all our attention. We don't feel cross, cranky or tired. I suppose that's why our sales are good."

That afternoon the president of the big store walked into the Cantilever Shop and asked a salesman to explain the features of Cantilever Shoes.

The Cantilever salesman took a shoe and bent the sole at the shank, showing how the shoe

conforms to the human foot, even to having a flexible arch like the foot. He said, "the arch of the foot should flex with every step, according to nature, yet ordinary shoes are made rigid by a concealed metal shank-piece that forbids free movement of the muscles. There is no rigid shank in Cantilevers. The 'waist' is designed to lug the instep, the shoe fits and supports the arch restfully. The flexibility allows the arch muscles free play and this, together with the natural lines of the shoe, permits perfect circulation.

"It is important to allow the foot muscles to exercise, to keep well and strong. The forepart of a Cantilever Shoe is shaped to look well, while allowing the toes to lie in their normal position. Cantilever heels are moderately high—high enough to be smart, without throwing the posture of the body out of balance as exaggerated heels do, causing unnatural pressure and strain on the nerves and the internal organs. By wearing Cantilever Shoes a woman avoids headaches and backaches, irritability and nervousness. She is brighter and happier."

"The subject is of great importance to the business woman who is required to stand during the greater part of the working period. The tired feeling often complained of at the end of the day's work may be attributed to ill-fitting shoes."

—Dr. Wilmer Krusen, head of the Department of Public Health of Philadelphia.

"Pain is a great foe to good looks. Comfort works just the other way. If you are comfortable, you are apt to be pleasant, and pleasantness and prettiness are often synonymous terms. Eliminate as many of your worries as you conveniently can—and your tight shoes!"

—Grace Margaret Gould on "Good Looks" in Woman's Home Companion.

"Working women are the worst offenders. It is the girls who are on their feet most who persist in wearing the highest heels. Sensible women have learned that they can increase their efficiency and even earn bigger salaries by wearing shoes built for solid comfort and health."

—Dr. Evangeline W. Young, of Boston.

## Progressive Health Program in Missouri

The six recommendations regarded as vital to the future of public health work in Missouri are based upon a series of partial and general surveys of the state and present all the advantages of right method in state health work. These recommendations include:

An amendment to the Public Health Act whereby counties of 25,000 population and over should employ an all-time health officer.

The passage of a law to prevent the marriage of mentally defective persons.

An Act to require the recording of all marriages in the Central Bureau of Vital Statistics to complete the valuable statistical information.

A new sanitary engineering act whereby the State Board of Health may be able to insure a safe quality of drinking water dispensed to the public, the proper disposal of sewage and the facilitating the abatement of insanitary conditions.

The Medical Practice Act should be amended to require an annual registration of all licentiates, making it possible to know at all times the location of a practicing physician and as a means of dispelling illegal and disreputable practitioners.

Adequate appropriations must be forthcoming for properly pursuing Public Health work, for the development of local health organizations and for the promotion of health education.

The biennial report just issued, covering 1919-1920 sets in array all the facts brought out in the intensive health study conducted in the state during that period.

## Inefficiency of Efficiency Experts

Good health is generally recognized as an almost indispensable requirement of a proficient worker, says a recent editorial in the *Journal of the American Medical Association*:

The investigations that have been inaugurated in recent years by the comparatively new science of industrial hygiene have made it increasingly clearer that even slight indispositions, not to mention more pronounced lack of physical stamina, are often sufficient to lower the output or degrade the quality of the work of laborers in many fields of industrial activity. Hence the growing concern of those interested in productivity for the physical welfare and personal well being of the person who produces. In a recent address, Holmes of the University of Kentucky has struck a timely note, on the other hand, regarding the failure of many of our "giant efficiency ex-

perts" to apply their principles of efficiency to their own living. Now and then, when the public becomes acquainted with the unexpected breakdown of a great leader of men at an early age, one is impelled to ask whether he failed to apply to himself the same standards of concern for efficiency which he set before his employees.

In speaking of the occupational failures of the "experts," Holmes reminds us that their principles of efficiency are frequently not applied to their own living. Big business, he adds, cannot long be done efficiently on artificial stimulants and by flabby muscles and shortness of wind. In the struggle for business, only the strong survive. Today, when there is a great need of capable leaders, it is essential to preach the lesson that even the keenest intellect is not immune from the action of physiologic laws. Even the "experts" must sometimes be admonished to practice what they preach.

## Junior Red Cross Establishes Hospital

A hospital and clinic for the care of school children with nose and throat infection has been established in Spokane, Washington, by the 16,000 school children who are members of the Junior Red Cross. The slackening of interest in Red Cross work following the war was met with the suggestion of this project, which fills a serious need. Money in the Junior Red Cross treasury provided full surgical equipment, paid the attending nurse, and now pays the surgeon and dentist originally supplied by the board of education. Furnishings such as towels, curtains, and bed linen have been made and renewed by members of the organization, and defective children in the schools have constructed furniture and rugs. Prior to May 27, 1921, four hundred and seventy operations had been performed in the hospital.

## Indiana Dental Association Makes Survey

A survey throughout the state of Indiana was made during the month of November for the purpose of securing data regarding the number of children with defective teeth. The Dental Association has the support of the State Board of Health and the Department of Public Instruction, and the active cooperation of each public health nurse who is working in the schools.

## The Commonwealth of Science

A recent statement of the purposes of the Rockefeller Foundation is a broad generalization of the objectives of scientific work.

"Science knows no national boundaries. It is a world product, a common fund of knowledge to which all nations contribute and upon which each may freely draw. To keep open the channels of communication by personal migration and by printed page, to encourage the training of specialists, to foster the growth of institutions, to stimulate research, to encourage the application of scientific knowledge to the needs of nations, communities, and individuals, are tasks upon the successful performance of which largely depends the progress of the world in economic efficiency, physical health, and international good-will. *It is the aim of the Rockefeller Foundation to have a part in this great movement by helping to increase the common store of knowledge about the cause of disease, and through demonstrations and the services of trained experts to diffuse this information as widely as possible among all peoples.* Thus does the Foundation seek to fulfill its chartered purpose 'to promote the well-being of mankind throughout the world.'"

## The American School Hygiene Association Meeting

Great interest attaches to the activities of an association which primarily interests itself in school health work and calls to its standard such advocates of hygiene as the representative physicians, dentists, nurses, superintendents, directors, supervisors, teachers, physical instructors, architects, psychologists, social workers, and parents as make up the membership of the American School Hygiene Association.

The program offered at the Thirtieth Congress of this Association covered the whole range of related subjects, and the speakers included such authorities as Arnold Gesell, professor of Child Hygiene, Yale University; Miss Grace Abbott, Chief, Children's Bureau, United States Department of Labor; Drs. L. Pierce Clark, John Sundwall, T. A. Storey, R. H. Halsey, and Edwin S. Ingersoll. The child health demonstration, sponsored by the American Child Hygiene Association, was outlined by Dr. Walter H. Brown, director of the Demonstration.

# Sherman's Polyvalent Vaccines

A more adequate and rapid immunity can be established with polyvalent vaccines than from an infection itself. SHERMAN'S POLYVALENT VACCINES rapidly stimulate the metabolism and defense of the body with a resultant prompt recovery in general acute infections.

Given early, bacterial vaccines almost invariably cut short the common pyogenic infections of the skin, mucosa joints and tissues;

Administered in advanced cases, they usually ameliorate or abbreviate the course of the disease;

Even when used as a last desperate expedient, they often reverse unfavorable prognosis.

The immunizing powers of stock vaccines are demonstrated by the prophylactic efficiency of typhoid vaccine. Bacterins made from selected, vigorous organisms are far higher immuno-producers than autovaccines prepared from feeble, degenerated organisms sometimes found in the patient's own specimens. Especially in acute cases, the PROMPT injection of a stock bacterin is decidedly preferable to the DELAYED injection of an autogenous one. The place for autovaccines is in chronic infections which fail to clear up under stock bacterins due to the prob-

able presence of some unusual bacterium.

Advanced inflammatory processes due to only one class of bacteria are rare, mixed infections being the rule. Therefore, COMBINED VACCINES, containing all strains likely to be present, give the best assurances of success; an unneeded variety of the bacterin is harmless and in no way weakens therapeutic response.

Thus the favorite invaders of the nose and throat are the pneumococcus, the streptococcus, the staphylococcus and the micrococcus catarrhalis, calling for Sherman's No. 40, and in chronic cases—when there is a foul odor produced by the Friedlander bacillus—Sherman's No. 36. In visceral infections, due chiefly to the colon bacillus with the pus cocci, Sherman's No. 35 is appropriate. In Neisser infections, if these organisms are not already allied with the gonococcus, the imminence of their entrance is so great that the rational combination is Sherman's No. 49.

When, particularly in grave cases, valuable time may be lost in securing the variety of vaccine especially recommended, it is always advisable to use the vaccine at hand which contains the predominant organism of the disease to be combatted.

## Sherman's 10 Mil Container

This package has many superior features which assure asepsis, prevent leakage and facilitate the removal of contents. It is constructed on the well known Sherman principle.

The vial is amply strong which prevents breakage so frequent with shell vials.

We are exclusive and pioneer producers of Bacterial Vaccines. Originators of the aseptic bulk package. Pioneer in elucidation, experimentation and clinical demonstration.

## Limitations of Army Gas Masks

THAT the army gas mask, while capable of giving protection against the deadly gases met on the battle field, does not protect against all the gases or atmospheres encountered in mines, in industries and in fire-fighting is the warning given by the United States Bureau of Mines.

The need of a knowledge of such gases on the part of city firemen has been especially emphasized by over-confidence in the capacity of the army type of gas mask to protect the wearer against industrial gases, an assurance that has probably arisen because soldiers were taught that the United States Army gas mask would protect them against all the gases they might encounter. This statement, true for the battlefield but not true for all industrial gases, including products of combustion, has been brought back by soldiers and spread generally among workers.

Furthermore, city firemen and mine operators have been circularized with letters and advertisements of army gas masks offered for sale by certain persons who made unreserved statements, probably through ignorance, that the masks would protect wearers in mines and burning buildings. The falsity of these statements was evident to the Bureau of Mines, which took steps immediately to notify the public that army gas masks have serious limitations, especially when used in fire fighting or in any place where unusually heavy amounts of poisonous gas are present. This warning has been verified by the actual experiences of some city firemen who have tried army masks. On the other hand the excellent qualities of the masks have also been demonstrated at fires.

Whether or not firemen should adopt the army gas mask for general use has been much discussed. Theoretically it would seem that the half-hour oxygen-breathing apparatus, which keeps out all gases and supplies oxygen, would be much safer than the gas mask for fire-fighting. But practical experience shows that firemen, as a rule, do not favor oxygen-breathing apparatus. To them it seems cumbersome and uncertain in action. The combination of oxygen cylinder, breathing bag, regenerator canister, valve and pressure gauge appears too complicated for the rough and ready work of fire fighting. Although such apparatus has been on

the market for a number of years, it is seldom put into practical use, even when on hand, at fires. Firemen prefer to take their chances unencumbered, or at most simply to tie a wet handkerchief or towel over the nose and mouth to keep out some of the smoke.

Therefore the utility of the gas mask must be considered from the practical point of view rather than the theoretical. A review of the many reports of tests in experimental fires by city fire departments shows: That firemen are favorably impressed with the simplicity of the gas mask and will wear it; that in the great majority of these tests it protected the eyes and throat from irritating smoke and was a great improvement on sponge respirators and wet cloths; that the mask did not encumber the wearer or retard his effectiveness in fire fighting; that no special training was required in learning how to use the mask; that in comparison with the oxygen-breathing apparatus very little attention is required to keep the gas masks in good condition.

These experiments by fire departments corroborate the experiments of the Chemical Warfare Service and of the Bureau of Mines in proving conclusively that the army gas mask, when fitted with a canister containing cotton filter pads, activated charcoal, and soda lime, effectively filters irritating smoke particles, and, in addition, protects against most chemical fumes in the concentrations likely to be met in fires.

However, in using the army mask the following serious limitations must be kept in mind: It furnishes no oxygen; hence it should not be worn into a place where a safety lamp or a fireman's oil-burning lantern will not burn; it should not be used where there is reason to suspect carbon monoxid, as in smoldering fires in basements and other confined, unventilated spaces, and especially in confined places where broken illuminating gas pipes add carbon monoxid to the air; it offers very poor protection against ammonia; finally, the army mask may break down in unusually high concentration of poisonous gases. It was originally designed for outdoor use, where the poisonous gases are considerably diluted with air. Caution must be used, therefore, in going into rooms where the concentration of the accumulated gas may be great

enough to pass through the mask.

Perhaps the most serious limitation of the army mask for fire fighting is its inability to protect against ammonia and carbon monoxid. Although special ammonia canisters are now available commercially, and carbon monoxid canisters soon will be available, the fire fighter does not know in advance what gas or combination of gases he may find. Many buildings contain ammonia refrigerating plants, and all cities outside the natural gas belt are piped for artificial gas containing carbon monoxid. The fireman, therefore, must have, in a single mask, protection against all these gases. Enough progress has been made by chemists working under the direction of the Bureau of Mines and subsequently in the Chemical Warfare Service in the development of an absorbent for carbon monoxid to raise the hope that a combination canister for a fireman's mask, which will protect against smoke, ammonia, carbon monoxid, and practically all chemical fumes, will soon be commercially available. When this is accomplished, a fireman can be protected in any atmosphere where a safety lamp will burn.

Since the ordinary army gas mask can not protect the wearer from the poisonous gases in a burning mine, the Bureau of Mines recommends the use of self-contained oxygen-breathing apparatus by men doing rescue work in mines.

Detailed information regarding the utility of various types of gas masks and breathing apparatus in the presence of poisonous and asphyxiating gases encountered in fighting fires and in burning mines is given in Technical Paper 248, which may be obtained from the Director of the Bureau of Mines, Washington, D. C.

### Organize New Health Bureau in New York City

Three Jewish health agencies have united in the support of a bureau to give to poor Jews free information and advice about physicians and hospitals. They are the Jewish Consumptives' Relief Society, represented by Dr. Ch. Spivak; the Joint Board of Sanitary Control, represented by Dr. J. M. Price; and the Social Service Department of the Free Synagogue, represented by Dr. Sidney Goldstein. This health bureau, which will be chiefly devoted to giving personal information, will also arrange lectures and publish hygienic literature in Yiddish.

## When the plane of metabolism must first be raised

HUNDREDS of experiments in animal nutrition have proved the great value of yeast in the growth-producing dietary. One of the most striking descriptions of its importance is given by a man pre-eminent in the field of physiological chemistry:

"A scrawny, lethargic animal, rapidly dwindling in size, with unsleek coat and evident malnutrition, will completely change its appearance and responses in a few days at most on a diet unchanged except for a tiny bit of yeast."

It has been found that not only the brewers' yeast usually utilized in laboratory experiments, but also the ordinary baker's yeast has extremely important properties. One of the outstanding qualities of this yeast is that its unusually high vitamine content renders it especially valuable in dietetic troubles where the plane of metabolism must first be raised before the patient can safely ingest a larger quantity of food without suffering from overeating, and where it is unwise to stimulate the patient's metabolism by exercise.

"In such cases," says a leading physiological chemist, "yeast appears to offer the best means for furnishing a relatively large quan-

tity of the water-soluble vitamine together with a comparatively small proportion of calories."

In the American Journal of Physiology for March, 1919, will be found a full account of the experiments made with Fleischmann's Yeast as a food for the growing organism. The experiments were carried on in the Laboratory of Physiological Chemistry at Jefferson Medical College, and they bear out the statement that yeast, by furnishing the water-soluble vitamine, raises the plane of metabolism rapidly.

In administering Fleischmann's Yeast the usual dosage is one cake t.i.d., plain or dissolved in water, milk, fruit-juices or beef-tea. As whole milk is the most important source of the fat-soluble A vitamine a combination of yeast and milk offers a rich supply of both vitamines. If the patient is troubled with gas it is advisable to treat the yeast first with boiling water.

Physicians can secure fresh supplies of Fleischmann's Yeast from the local grocer, but if they prefer they may write direct to The Fleischmann Company in the nearest large city and a supply will be mailed on the days wanted.

THE FLEISCHMANN COMPANY,

701 Washington St., New York

## Preventive Medicine and Hygiene

A new and revised edition of Rose-nau's standard work on "Preventive Medicine and Hygiene," including chapters on sewage and garbage by Professor George C. Whipple of Harvard, vital statistics by John W. Trask, and mental hygiene by Thomas W. Salmon, has just been made available.

The work is so well known and widely used that it seems unnecessary to develop in detail its content and purpose. It was written to include the medical and related sciences which form the foundation of public health work. The book is divided into two parts, that which deals with the individual or person (hygiene), and that which deals with the environment (sanitation). A number of new subjects have been added,—oral, ocular, and personal hygiene, the vitamins, rural sanitation, etc. Much of the book has been rewritten and extensive changes made.

D. Appleton and Company, New York, 1921.

## Two New Insurance Manuals

The information of the general public with regard to the principles of insurance is notoriously uncertain. The average man, even the average business man, will usually be found not to realize the extensively broadened scope of insurance practice, or even able to analyze the particular form of protection for which he is paying. Two books recently published have great value as aids to the comprehension of the more important forms of insurance. The one, "Insurance Principles and Practice," by Robert Riegel and H. J. Loman,<sup>1</sup> both of the University of Pennsylvania, coordinates those features of insurance which are common to all its branches and analyzes personal insurance from the viewpoint of the buyer. Of particular interest to business men and to industrial physicians are the chapters on the newer developments of recent years in compensation insurance, the factors controlling rates and the methods of regulating reserves.

While "Medical Examination for Life Insurance," by Thomas L. Lister,<sup>2</sup> is designed to afford principles of the evaluation of lives which enable the practising physician to correlate the social and hereditary factors with his clinical experience, it is of interest to the general reader to learn the underlying principles governing the insurability of a life. It

gives a rational perspective on temperament, habit, status, and tendency in the proposer for insurance and explains why the medical examination is only a part of the general assessment of life expectancy in a given case.

2. Longmans, Green & Co., New York, 1921.

## Tuberculosis in Industry

The January 1922 *Bulletin* of the National Tuberculosis Association is devoted to the consideration of the industrial tuberculosis problem and indicates the likelihood of a further reduction in the prevalence of tuberculosis in industry through its early discovery, adequate treatment, and effective follow-up care. An article by W. I. Hamilton, industrial research secretary, describing the studies in occupational tuberculosis, financed jointly by the Federal Board for Vocational Education and the National Tuberculosis Association offers promise of a solution to the question as to what industries or particular processes may be considered suitable or unsuitable for arrested cases of tuberculosis. The study will involve an investigation of the factors due to the personality of the worker, including his physical status, factors due to the condition of the work, to

the materials and process, and to the working place.

Other articles deal with the industrial clinics of the New York City Department of Health, the garment factory conducted by the Committee for the Care of the Jewish Tuberculous employing arrested cases of tuberculosis exclusively, the activities of the Union Health Center under the Joint Board of Sanitary Control, and the industrial health educational program of the New York Tuberculosis Association.

## The Teaching of Hygiene in the Grades

The book is an exposition of the history, literature, and methods of teaching hygiene to children. It includes chapters on: The fundamental importance of hygiene in the curriculum; the status of the teaching of hygiene; the goals of instruction; suggestion of method; important problems and their solution, and the teaching of hygiene in the rural school. The last chapter is by far the most important although all chapters are written quite well.

A complete bibliography and a selected list of reference books are added at the end of the book.

Houghton-Mifflin Company, New York, 1921.

# Hookworm Control Experiments

A study of the factors influencing the life of the hookworm outside the human body was conducted during the summer of 1921 under the direction of an expedition sent to Trinidad, British West Indies, by the School of Hygiene and Public Health of the Johns Hopkins University, working in cooperation with the International Health Board. The work was carried out in an area where sugar-cane cultivation predominates and where 70 per cent of the people are infested with hookworm.

Full reports of the various investigations will appear in the *American Journal of Hygiene* but a summary of the significant findings is given in *Science* by Doctor W. W. Cort, director of the expedition. Epidemiologic studies of the factors involved in the spread of hookworm disease in two limited areas comprised one phase of the investigation, while laboratory studies were carried on dealing with the relation of the chicken and pig to the spread of the disease, the factors influencing the hatching of the eggs, the vertical and hori-

zontal migrations of the infective hookworm larvae, and the length of life of the infective larvae.

The provision of an adequate number of latrines accompanied by an educational campaign resulted in considerable reduction in soil pollution in a short period. When chickens ingested human feces containing hookworm eggs only a very small proportion of such eggs produced infective larvae, a condition distinctly favorable to hookworm control. Eggs ingested by pigs, however, developed infective larvae just as readily as those passing through the human digestive tract. Hookworm eggs hatch in ashes as well as in soil, but where eggs are buried 4 or 5 inches in a clay loam soil, only a few larvae developed. Under certain conditions mature larvae can migrate to the surface from such a depth. Mature hookworm larvae do not migrate actively from their place of development, though they may be carried considerable distances by water and otherwise. The length of life of the larvae never exceeds six or seven weeks.

# KOTEX

*“Oh yes—  
and a box of Kotex, too”*

IT is now as easy to buy sanitary pads without embarrassment as to buy hair nets or face powder. The one word “Kotex” has made it so.

“A box of Kotex”—that is all the conversation necessary. Nearly all stores and shops that cater to women sell Kotex. From New York to San Francisco. Dry goods, department, and drug stores. Everywhere.

Kotex are large and perfectly absorbent. They are made of Cellucotton. Nurses in France first suggested their manufacture for universal use. Kotex are inexpensive—cheap enough to throw away. So easy to dispose of that they solve a laundry problem. Directions inclosed in every box. New sanitary habits are being formed everywhere by Kotex.

If it is not convenient to shop today, order Kotex by telephone. Once familiar with Kotex, its use will be continued.

Ask by name for Kotex.

Cellucotton Products Co., 208 S. La Salle St., Chicago  
New York: 51 Chambers St. Factories: Neenah, Wis.

*Regular Size*

**12 in box for 60c**

*Trial box of 12 mailed prepaid in plain wrapper for 65c*

*Large Size*

**6 in box for 45c**

*Trial box of 6 mailed prepaid in plain wrapper for 50c*

*Kotex cabinets are now being installed in women's rest-rooms everywhere — hotels, office buildings, restaurants, theatres and other places — from which may be obtained one Kotex with two safety pins, in plain wrapper, for 10 cents.*

## Inhalation of Injurious Dust

**A**N INVESTIGATION of the various types of respirators used by workers in numerous industries in preventing the inhalation of injurious dusts is to be undertaken at the Pittsburgh experiment station of the United States Bureau of Mines.

Stone dusts and metal dusts that are breathed by miners, stone cutters, and metal polishers have been the cause of much pulmonary diseases, incapacitating many workers and at times resulting in early deaths. While the best preventive is to eliminate formation of dust or to stop it at the source, nevertheless numerous situations exist where respirators are serviceable in preventing inhalation of injurious dusts suspended in the air. The respirators are mostly of the "pig snout" type that form a cap of metal, rubber or cloth over the mouth and nostrils so as to cause air filtration through a sponge, paper, fabric or metal gauze.

The finest particles of dust, of a size far too small to be seen by the unaided eye, are the ones that lodge in the lungs and do most damage. At present little is known of the merits of the different filters used for respirators, and workmen often prefer to protect themselves with a towel or handkerchief tied around the face. In the proposed tests by the Bureau of Mines fine particles such as compose tobacco smoke and fine mineral dusts suspended in air will be filtered with the different materials. The relative effectiveness of the filters will be noted as well as their resistance to passage of air and tendency to clog. It is proposed that the information obtained be used to design more effective dust respirators.

The tests will be conducted by S. H. Katz, assistant physical chemist, and L. J. Trostel, junior chemist, under the direction of A. C. Fieldner, supervising chemist.

## Rural Schools Neglect Eyesight

**E**YE tests are efficiency tests. Bright children become dull because of defective eyesight and children remain handicapped and backward for lack of having their eyes tested and the proper corrective glasses applied, the *New York Times* quotes Dr. Thomas D. Wood, college physician of Teachers College, Columbia University, as saying in criticism of the laxity of visual standards in the state of New York.

More than 21 per cent of American rural school children have eye defects, according to Dr. Wood, who said that the health work in rural schools is just being developed, but that enough has already been done in a few states and in a few rural schools to demonstrate how important and how practical are these forms of health work.

Of 347 schools in town, of which eighty-nine may be considered rural schools, 66 per cent do not test eyesight. In 1,262 rural schools reporting from eighteen states, eyes are not tested in 76.7 per cent.

The eye as an optical instrument is almost never perfect mechanically. We find from examination of the eyes of school children that 25 to 40 per cent have defective vision which requires either correction by glasses or readjustment in class work. Most of these cases can be largely corrected by properly fitted glasses.

Educational experts in this country have come to an increased appreciation of the importance of the eye in school work, according to Dr. Wood. The United States Bureau of Educa-

tion has just signified its approval of eyesight conservation work. Through Dr. John J. Tigert, Commissioner of Education, recently elected a member of the Board of Councillors of the Eyesight Conservation Council of America, with central headquarters in this city, the bureau will work with a group of leaders in eyesight conservation.

Some medical authorities have attributed epileptic and epileptiform seizures to abnormal eyes, said Dr. Wood. It is commonly conceded that defective eyes with imperfect vision cause headache through the forehead or the back of the head, or both, blurring of sight, though in farsightedness with eye strain vision may be exceptionally good, especially for distant objects; nausea and dizziness, sometimes disturbance of digestion, with resulting malnutrition; nervous exhaustion, nervous irritation and lack of nervous control, shown in muscular twitching of face, arms and legs, or in winking frequently and squeezing the eyelids shut; mental inability to grasp an idea presented through the eyes; retardation in school, and, in rare cases, convulsions.

The routine tests of vision and hearing can best be made by the teachers, said the doctor, as these tests involve to an unusual extent mental and educational, as well as health, factors and requires a knowledge of the pupil possessed by the teacher as well as simple methods of examination which all capable teachers can easily learn. The introduction of the eyes tests in rural schools, Dr. Wood said, would not necessitate a large outlay of money.

## Is Tuberculosis Re-Infection Probable?

Our mode of attack on the tuberculosis problem has changed with the acquisition of new knowledge confirming or destroying commonly accepted theories of the day. To treat clinically active cases of tuberculosis was the principal measure in the early anti-tuberculosis program. Later emphasis was placed on measures for the prevention of infection, and when the ubiquity of tuberculosis infection was recognized, increasing individual bodily resistance was stressed to ward off the disease. Confident adherents of the theory that adult disease is due to the recrudescence of childhood infection have gone so far as to urge the impossibility of adult re-infection, which has of course had a profound effect on the measures designed to prevent infection. Despite the apparent plausibility of such a stand, data gathered by various investigations bring into question its truth and authenticity. An excellent example is the data gathered in the study of 229 widowed patients admitted to the Rhode Island State Sanatorium, of whom 93, or 40 per cent, lost their consorts by death from tuberculosis, a tuberculosis mortality over three times that of the married people of the community. The significance of this study is reported by H. L. Barnes in a recent issue of the *American Review of Tuberculosis*.

## Veterans' Bureau Maintains Tuberculosis Clinic

A tuberculosis clinic for ex-service men was opened recently at the Veterans' Bureau, 23 West 43rd Street, New York City. The Clinic has been established at the suggestion of the New York Chapter Red Cross which has found many cases of men who developed the disease while in the service, but who are unwilling to go to a sanatorium for treatment.

The Veterans' Bureau has also recently established in New York a mental clinic where men who are not seriously enough affected to be sent to institutions can receive treatment. It is estimated that eighty per cent of the men coming to the Medical Social Service Department of the New York County Red Cross each year, about one thousand, are mentally unbalanced and in need of such treatment as the new clinic affords. The Red Cross is assisting this phase of the Veterans' Bureau work by looking up the family and social histories of all the men coming to the clinic.

# Nurses Lightweight Portable Scale

for Weighing and Measuring Babies, Children or Adults at Rural Schools, Welfare Stations and General Field Service

Can you imagine a handier equipment than a scale LIGHT ENOUGH for you to handle in transportation, yet possessing every worth-while scale feature. You can set the Continental scale up in less than two minutes. There is no lighter scale made, yet none is more efficient.

## CONTINENTAL Nurses Lightweight Portable Scales

are designed and built to serve the rigid requirements of traveling nurses. Every Continental scale is designed for a given purpose and meets it thoroughly and efficiently. Continental Scales are accepted everywhere, for professional use—and there's a reason!

Learn more about the Continental Nurses Lightweight Portable Scale. The "Continental Seal of Accuracy" is your quality protection and guarantee.

Literature on the Continental Nurses Lightweight Portable Scale is yours for the asking. Write for it today.

### CONTINENTAL SCALE WORKS

2122 West 21st Place, Chicago, Ill.

72 Murray Street, New York City

Model No. 526  
Capacity 240 lbs.  
Graduated in Ounces.

With carrying case, ready for any method of transportation.

Sent on approval if desired

## Electrically Lighted Surgical Instruments

Particularly adapted for bedside use. Sold by all leading surgical instrument dealers. See that instruments are stamped "E.S.I. Co."

Nasopharyngoscope—Holmes  
Urethroscopes—Young, Swinburne, Koch, Valentine  
Cystoscopes—Braasch, Kelly  
Pharyngeal, Laryngeal and Oesophageal Specula, Bronchoscopic Instruments—Jackson, Lynah  
Nasal Specula

### General Diagnostic Outfit

A selection of instruments most commonly used by the General Practitioner, in a convenient case with either battery or socket current controller.

Illustrated catalogue upon request

**Electro Surgical Instrument Co.**  
ROCHESTER, N. Y.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more promptly and more permanently effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

Information, Sample and Literature from

**Schering & Glatz, Inc.**  
150 Maiden Lane NEW YORK

## What May Be Considered Adequate Color Vision

The need for adequate color tests to detect color blindness is treated by Captain E. J. Grow, Medical Corps, United States Navy, in a reprint from the United States Naval Medical Bulletin in *The Military Surgeon*. Contrary to popular opinion, color blindness is both acquired and congenital, states Captain Grow. It may be acquired, as in the case of the young naval officer who was temporarily color blinded by continued gazing at the reflection of the sun on a broad expanse of water.

Acquired color blindness is always met with in cases of optic atrophy. A loss of visual acuity is also experienced with the loss of color perception. Poisoning by chemicals or excessive use of alcohol or tobacco often produce color blindness. Color blindness from these latter causes may be cured if the case is properly treated.

As the degree of color blindness varies in persons, so acuity in color perception varies greatly in the normal individual. The person who cannot name the colors and has no occasion in his daily work to use them, but who recognizes the primary colors, represents the minimum. The other extreme of normal vision is represented by the person who can see violet as a distinct color in the spectrum. It is claimed that only one person in five thousand has sufficiently acute color perception to enable him to do this. Women in general average higher in color perception than men. Artists who have used colors for a considerable time become highly proficient and can see many tints that the untrained cannot see.

The Holmgren color test, involving the use of colored yarns has for a long time been the official test in the United States Navy. Although there are many valid objections to the Holmgren test and it is being rejected by many railroads, it has stood the test for forty years in the United States Navy, during which time no serious accident at sea could be attributed to defective color perception. The greatest defect of the test is that it does not detect those cases of color blindness resulting from a shortening of the red end of the spectrum. This is unfortunate for the double reason that this defect is common and that red is universally adopted as a danger signal.

The main objections to the Holmgren color test are that the color

blind person can guess at the colors by the luminosity of the yarn, and that it is too elaborate to be carried out by a person with little color vision knowledge.

The Jennings test, consisting of various shades of green and red yarn in separate boxes, and the Edridge-Green lantern test are considered too complex and too liable to error for the purposes of the Navy. The Edridge-Green bead test is considered excellent by Captain Grow.

## Revised Report on Children's Bureau

The National Health Council has issued a comprehensive report on the Children's Bureau of the United States Department of Labor. This report outlines the legal authority, history and development of the Bureau, its organization, current work, personnel, the Federal Child Labor

Law, and the Act for the Promotion of the Welfare and Hygiene of Maternity and Infancy. It was originally prepared on August 1, 1921, but with the passage of the so-called Sheppard-Towner Act, the scope and influence of the Children's Bureau has been so greatly increased and so much interest has been manifested in the Bureau, that the Council considered it worth while to revise the original report, many hundred copies of which had been distributed. The report on the Children's Bureau is one of five which have been prepared by the National Health Council concerning government bureaus dealing with public health. The others are about the Division of Vital Statistics of the United States Bureau of the Census, the Women's Bureau of the Department of Labor, the Division of School Hygiene of the Bureau of Education, and a general report covering the health activities of the government.

## The Hygiene of Buildings

WE HAVE in the past been more or less concerned about the concentration and general direction of light, and have gone to some trouble to secure illumination that is soft, that seemed sufficient, and could be focused on the job. Nowadays, however, the lighting and heating of modern buildings, schools, and halls are measured with mathematical accuracy. It is not sufficient that the light on one's desk appears to be normal. So important a matter cannot be left to chance, states the *New York Times* in describing how the light falling on a desk, for instance, is measured by means of an ingenious device known as a photometer, which gives the precise candle power of the illumination, whether it be from the sun or an electric bulb.

The instrument consists of a telescopic device containing a small electric light, which is used as a unit of measure. It is equal to the light of a standard candle at a distance of one foot. A white disk is then laid on the desk and the barrel of the telescopic device slid back and forth until, as observed through the telescope, the light equals that of the standard of measure. The relation between the two lights is then recorded on a dial.

It is often found that the lighting on the desk in some obscure corner of an office or on a desk in a dark school room is only one candle, or that of a single candle held one foot away. Too much light is also bad

for the eyes. The glare from a polished desk will also serve to exaggerate the light. As a matter of fact, the light on one's desk should be equal to that of nine foot candles, or the illumination of nine standard candles at a distance of one foot. In modern factories where correct lighting often affects the product, these tests are very important.

The degree of moisture in modern buildings is also the subject of painstaking study. Tests are made with a wet and dry thermometer. It has been found that in rooms which have been crowded with large audiences the air is often dryer than that of the desert. The range of these tests varies widely, some rooms having but 10 per cent of moisture and others 60 per cent. It is still fondly imagined by some that a pan of water placed on a stove or radiator will add sufficient water to the atmosphere of a room. An office building may require several barrels of moisture in its air every day.

The exact quantity of air entering a room or building is scientifically measured by a fan deliberately balanced, whose revolutions are indicated on a dial. The speed of the fan is read, and the amount of air calculated with reference to its speed is the size of the intake through which the air is admitted. Those working in rooms scientifically lighted and ventilated are found to work with much increased efficiency.

# LOESER'S INTRAVENOUS SOLUTIONS

**INTRAVENOUS MEDICATION**, an evolutionary step toward rational medicine and improved clinical results.

**DEMANDS** solutions of higher standard of scientific accuracy for safe and practical employment.

**ANTICIPATING** this demand, we devoted years of intensive study, developing a higher branch of pharmaceutical art.

**RESULTS**— Scrupulous laboratory routines, exacting chemical, physical and toxicity tests, producing intravenous solutions that are the established standard of comparison.

**AVOID SUBSTITUTES** with fanciful names and ambiguous statements as to contents, offered with low price inducements.

For sale at your local druggist or physician's supply house

*Descriptive Literature, Price List, "Journal of Intravenous Therapy," will be sent to any physician on request.*

## NEW YORK INTRAVENOUS LABORATORY

100 West 21st Street

NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions for the Medical Profession Exclusively.*

# AMERICAN COLLEGE OF PHYSICAL EDUCATION

*Accredited—Co-educational*

**T**HE profession of Physical Director and Playground Supervisor is in the ascendancy. It makes possible the American ideal of "Efficiency through Fitness." One-half of the states require teaching of physical education. Therefore, Colleges, Universities, Public and Private Schools, as well as Summer Camps, Athletic Clubs, Industrial, Social and Community Centers, Banks, Manufacturing Plants, Department Stores, Y. M. and Y. W. C. A., are making constant demand for more trained men and women. The American College prepares and places through its free graduate bureau large numbers of these workers each year.

The American College offers two year, three year, and degree courses. We also offer a graduate placing bureau for the benefit of not only the graduates, but also for the employers of teachers of physical education. This service is rendered without cost to the student or the employer.

NEW TERM OPENS February 7, 1922.

Write for catalog and book of views.

Address, Dept., N. H., 4200 Grand Blvd., Chicago, Ill.

## FROM THE FIELD

The American Red Cross has discontinued the publication of all its national and local periodicals and is publishing in their place a weekly newspaper, *The Red Cross Courier*.

The Third American Congress of Infant Welfare will be held at Rio de Janeiro, August 27 to September 5, 1922, on the centennial of Brazilian independence.

*The Journal of Orthopedic Surgery*, Boston, Mass., will become a quarterly publication in January, under the name of *The Journal of Bone and Joint Surgery*.

The Attorney-General of Wisconsin has interpreted the state law to mean that all restaurant and hotel employees are under the jurisdiction of the State Industrial Commission.

A new cardiac clinic which will give Sunday as well as week-day service has been opened in the Cook County Hospital Dispensary, Chicago, with Miss Jean Wilson in charge.

Adolescent girls constitute the only group in which the tuberculosis death rate has not declined, according to statistics compiled by the Metropolitan Life Insurance Company for the ten year period 1911 to 1920.

Prof. Ernest Fuchs will deliver a series of twenty illustrated lectures in March at the College of Physicians, Philadelphia, on "Ocular Pathology."

Dr. T. C. Merrill, of New York, is joint author with H. Voille of a series of child health studies made while Assistant Medical Director of the American Red Cross in Europe. "Les grande formules modernes de la Nutrition, Leurs applications pratiques," one of the series, has been reprinted from *La Presse Medicale*, November 23, 1921.

Only 8.26 per cent of the rural population of the United States is provided with adequate health service, according to data obtained by the Rural Sanitation Office of the Public Health Service from the state departments of health.

E. Vernon Hill and John J. Aeberly, M.E., of the Chicago Department of Health, are authors of an article in the December *Heating and Ventilating Magazine* on "What About Ozene?"

Bailey B. Burritt, General Director, New York Association for Improving the Condition of the Poor, has an article on "The Place of the Nutrition Worker in the Health Program" in the December issue of the *Journal of Home Economics*.

The Fifth Annual Conference on Physical Education, under the general auspices of the Bureau of Education, will be held in Chicago at the time of the annual meeting of the Department of Superintendence of the National Education Association, February 24 to March 2. The progress of physical education organization is seen from the fact that six years ago only three states had any reference to it in their statutes while today 28 states have laws providing for some measure of physical education.

The Brazilian law regulating the importation, sale or furnishing of poisonous substances is to be enforced, as witness a recent decree of the President. According to this law, poisonous or narcotic substances, such as opium and its derivatives, cocaine, and similar drugs, may not be cleared through the customhouse, or be delivered when coming through the mails without a previous permit from the National Department of Public Health. The same law contains a provision for the establishment of sanitariums for toximaniacs, the treatment given to be both medical and correctional.

Fire hazards have increased in school buildings with the advent of the manual training and domestic science class, the motion picture machine, and the general use of schools as social centers, according to a writer in *The American City*. With 80 per cent of the school buildings in the United States fire traps and schoolhouse losses unusually heavy during the past year, the belief is increasing that insurance rates on school houses have not been advanced

in keeping with the increased hazards.

A Federal Board of Hospitalization has been organized for the purpose of coordinating the separate hospital activities of the medical department of the Army, the bureau of medicine and surgery of the Navy, the Public Health Service, St. Elizabeth's Hospital, the National Home for Disabled Volunteer Soldiers, the Office of the Commissioner of Indian Affairs, and the United States Veterans' Bureau. Brig. Gen. Charles E. Sawyer, the President's private physician, has been appointed Chief Coordinator.

A bill introduced by Monsieur De-strée, Belgian minister of science and art, provides for compulsory physical education in all educational institutions under government supervision or subsidized by the state. Young men not attending any educational institution are required to register for physical training with certain authorized societies, and communes of more than 5,000 inhabitants are obliged to install and maintain a playground and gymnasium accessible to the children in the public schools and to members of the recognized societies.

The first day nursery in Ecuador was opened October 9, 1921, in Guayaquil in a reinforced concrete building erected through the generosity of the citizens and through the efforts of Dr. Juan Bautista Arzube Cordero and other members of the Puericulture Society.

With its October number, *The Hospital*, a leading English weekly paper, becomes a monthly journal with the title *Hospital and Health Review*. The change in title and form indicates a broadening of its field to include public health activities.

A bill for social insurance in France provides for the free choice of physician by the insured, necessity of contracts between the insurance companies and the local or national organizations of physicians, a control board of equal numbers of officials and physicians, and insurance for wage earners with incomes up to 10,000 francs. The employers retain 5 per cent of the annual wage to pay the dues. The bill, which forms a volume of 228 pages, has been distributed to the members of both houses. Cahen Salvador, a Conseiller d'Etat in the Labor Department, drew it. Boudin, in *Paris Medical*, analyzes the bill's provisions.

## Radiant Heat vs. Convective Heat

In industrial as well as private practice there is frequent need for the application of heat, particularly in such cases as neuralgia, neuritis, sciatica, mastoiditis and rheumatism.

The common practice was to employ some form of convective heat such as poultices, hot-water bottles, jacks, etc.

Today the profession recognizes the greater benefits derived from Radiant Heat, particularly as exemplified in

### The New Thermolite

This new method of heat application insures deeper penetration, resulting in a marked hyperemia, with a decided sedative and analgesic effect derived from reflex action on the peripheral nerve endings.

The new Thermolite radiates only parallel rays, with no focal point to cause burning.

The outer twelve-inch aluminum reflector contains a highly polished parabolic projector which in conjunction with a special 375 watt 120 volt lamp furnishes a parallel penetrating beam of correct intensity that covers an area of about 300 square inches at operating distance (36 inches from reflector).

*A booklet illustrating The Thermolite in more detail will be sent free upon request.*

**H. G. McFADDIN & CO.**

42 Warren Street, New York City

## 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

Made only by

**Ground Gripper Shoe Company, Inc.**

Profits of wholesale dealers in Cuba must not exceed 10 per cent when they sell to retail merchants, and retail merchants in selling to the public are likewise restricted from making a greater profit, according to a degree signed by the President of the Republic initiated by the Secretary of Agriculture.

A committee to make a survey of the existing methods of treating injured employees and to make recommendations to assure injured workmen adequate treatment, just compensation for physicians and surgeons, and the restoration of the patient to a condition of efficiency in the shortest possible time has been appointed by Henry D. Sayer, Industrial Commissioner of New York and head of the State Department of Labor. Members of the committee are Dr. James F. Rooney, Albany, president of the Medical Society of New York; Dr. Eden V. Delphey; Dr. F. D. Jennings; Dr. A. R. Tilton, Chief Medical Adviser, Travelers Insurance Company; Dr. R. Lewy, Chief Medical Examiner for the Department of Labor. Stanley L. Otis, Director of the Bureau of Workmen's Compensation, New York, is secretary of the committee.

A new publication, *The Weekly Better Times Bulletin*, made its appearance January 1 in New York City. This is issued supplementary to *Better Times*, a monthly devoted to the charitable activities of New York City. George J. Hecht is editor of the new bulletin and Mrs. Gertrude H. Springer is managing editor.

According to a recent decision by the Attorney-General of Ohio, osteopaths have the right to sign death certificates. The ruling holds that "if the osteopath meets the educational requirements of the statutes" and takes the same examination in diagnosis as is taken by physicians, under the law he should have the same legal rights as are granted to physicians.

The Associated Medical Clinic which has been operated by the Children's Bureau has been transferred to the Department for the Prevention of Disease in the Children's Hospital, Eighteenth and Fitzwater Streets, Philadelphia. Dr. J. Prentice Murphy is in charge of the department, which includes a health clinic, diphtheria clinic, pre-school nutrition class, dental clinic and mothers' conference classes.

The United States government has stationed two physicians at the University High School, Oakland, Cal., for the purpose of studying the effects of the students' physical condition on their scholarship, attendance and conduct. About 100 students are examined weekly.

A life insurance company with headquarters in Boston is aiding in the movement initiated by the American Society for the Control of Cancer to spread information regarding cancer by having its agents deliver to policy holders a pamphlet published by its medical department on "Vital Facts About Cancer." During the past five years this company has paid \$1,379,778 for cancer claims.

Following several accidents to minors employed in hazardous occupations without labor permits, the Oregon State Industrial Accident Commission sent out letters to employers calling attention to the fact that the age limit under which a permit is required was raised by the 1919 legislature from 16 to 18 years. The maximum penalty for violation of the law by an employer is \$500.

Maternity nursing by visiting public health nurses has reduced deaths of mothers 60 per cent, the number of stillbirths, 70 per cent, and the number of infants dying under one month of age, 50 per cent, according to Dr. Louis I. Dublin in the December *Public Health Nurse*.

Interesting data concerning child workers in New York state is contained in a recent issue of *The American Child*. During the year ending June 30, 1921, 19,542 employment certificates and 629 vacation permits were issued in New York state outside of New York City by the health officers upon whom this duty rested. Illegal employment certificates were issued to 389 children and illegal vacation permits to two. Of the total number for whom there was age data, 63 per cent were 15 years old, 36 per cent 14. Less than two-thirds had completed the eighth grade and many of these had attended a year or more of high school. Approximately 86 per cent presented birth records, passports, or baptismal certificates as proof of age. Thirty per cent of the children examined for certificates had one or more physical defects, subnormal vision and decayed teeth forming 75 per cent of them.

The unification of international standards of antitoxic sera is the aim of a study which the League of Nations Health Committee is making. The United States is represented by the United States Health Service at Washington and by Dr. Rupert Blue, Assistant Surgeon General, stationed at Paris, who will be present at the conference. German scientists, Japanese, and representatives of European medical services are participating in the work.

The committee purposes to standardize in the various countries the methods of measuring the strength of antitoxic sera, thus avoiding confusion now current in the measuring strength for sera for such diseases as dysentery, tetanus, diphtheria, syphilis, meningococcus and pneumococcus. Standardization will also be of benefit from the standpoint of international trade in sera.

At a conference held in London in December the study of standards for sera for the various diseases was allotted to the different laboratories. The State Serum Institute at Copenhagen will aid in coordinating the studies. Other bodies which will cooperate are the Medical Research Council of Great Britain, Pasteur Institute of France, State Institute of Italy, State Institute of Warsaw, Hygienic Institute of Basle, Pasteur Institute of Brussels, Kitasato Institute of Japan, as well as Austrian and German organizations.

The National Tuberculosis Association has issued a cumulative author and title index of its transactions from the year 1905 to 1920. Ella Hoffman Ward had charge of the compilation, which was published in New York by the Association.

A labor accident law which provides for half pay for temporary incapacity arising from accidents or diseases produced by the laborer's work and for two years' pay for total incapacity was signed by the President of Ecuador September 30, 1921.

The seventeenth annual meeting of the American Red Cross was held at National Headquarters, Washington, D. C., December 7. The following officers were re-elected: President, President Warren G. Harding; vice-presidents, Robert W. DeForest and William Howard Taft; counselor, James M. Beck; secretary, Mabel T. Boardman. Eliot Wadsworth was elected treasurer to succeed John Skelton Williams.

## The American Dollar and "AMERICAN" Sterilizers

An advertisement worth the reading of any interested in the purchase of sterilizing equipment—and directed particularly to those seeking the most for their expenditure.

**W**ITH all eyes centered upon Price, the purchasing power of the American dollar has never been so taxed as it is today.

We sense that you are not immune to the price appeal in the purchase of your equipment. You are seeking the very most your money will buy—and rightly so. It is, therefore, a source of keen satisfaction to us to know and be able to prove that

**AMERICAN**  
THE PRODUCT OF SPECIALISTS  
**AMERICAN**

### Sterilizers and Disinfectors

at present prices represent the greatest Sterilizer and Disinfectors value obtainable. Notwithstanding the fact that they cost more to manufacture, due to the use of finer materials, more searching tests, more scientific and precise shop and machine work, more exacting inspection, and are consequently worth far more to the owner, they are sold today for less per unit of value than any similar apparatus made. Greater skill, greater specialization, greater achievement do not make the "AMERICAN" cost more—they do make it worth more.

And the purchase price, low as it is, is greatly lessened in the after years of uninterrupted service because of low maintenance and operating costs. Your dollar has been creditably spent when it goes for "AMERICAN" apparatus.

Descriptive bulletins, engineering data and specialists' counsel are free for the asking.

## CASE RECORD FORMS

### Keeping Up to Date

**T**HE System of Hospital Case Record Forms devised by the American College of Surgeons has been in use in many hospitals for upwards of two years. From time to time new forms have been added as experience has shown the need. The College has issued a new bulletin covering these additions which has been mailed to all hospitals.

The Faithorn Company supplies these forms, well printed, on durable bond paper, at favorable rates. All new forms are added and revisions made as they are developed by the College. Rates on new forms are the same as given on other forms in our catalog.

*Please note*—We prepay all shipments, thus distance is no barrier to buying of us, and you receive the forms with no more inconvenience than if ordered locally.

### Filing Devices

Next in importance to the keeping of accurate case records is an adequate system of filing. We supply loose-leaf binders for temporary filing, and filing cases with indexes for permanent file.

*If you have not received our catalog and price list, we will be pleased to send upon request*

Frank R. King, Plumbing and Domestic Sanitary Engineer of the Wisconsin State Board of Health, is the author of a series of articles on "Successful Sewage Disposal Systems for Farm and Rural Homes and Schools" which are appearing in *Domestic Engineering*.

"Helpful health hints" are being scattered over the continent by the *Wireless Telephone Health Bulletin Service* inaugurated at the beginning of the new year by the United States Public Health Service. These bulletins are sent out bi-weekly, Tuesday and Friday, at 9 p. m., from the Naval Radio Station at Anacostia, Va.

The Wichita, Kansas, police force is to be covered by group insurance, providing for \$3,000 life insurance and \$20 a week health and accident insurance for each member. A \$5 a month increase for each officer, which was authorized in an ordinance recently enacted, provides the premium fund.

During the past year the United States Public Health Service has opened seventeen hospitals. It is also preparing nine other hospitals, four of which will be opened about May 1. Hospitals established recently include the former Navy Hospital at Gulfport, Miss.; Jackson Park, Chicago; Colfax, Iowa; Portland, Ore.; and the Edward Hines Junior hospital at Maywood, near Chicago; Fort McKenzie hospital at Sheridan, Wyo.; and the one at Fort Logan, Little Rock, Ark. The Navy hospital at Las Animas, Col., will be taken over soon. These hospitals increase the capacity of all service hospitals to 22,600.

The National Health Exposition was held in Louisville, Kentucky, February 1-9, under the auspices of the United States Public Health Service, the State Board of Health of Kentucky, the Jefferson County Board of Health, and the Health Department of the City of Louisville. Exhibits on hospitalization, nursing, dentistry, medicine and pharmacy were on display.

At an institute conducted by the U. S. Public Health Service, in connection with the Exposition, speakers included Dr. Milton J. Rosenau, Dean of the Harvard School of Public Health; Dr. Josephine Baker, Director of the Department of Child Hygiene, New York City Board of Health; Dr. Wm. A. Evans, former

Health Officer of Chicago and public health editor; George T. Palmer, President of the Illinois Tuberculosis Association; Dr. Frederick E. Greene, Secretary of the Council on Health and Public Instruction, American Medical Association; Dr. Valeria H. Parker, Director of the Inter-departmental Board of Social Hygiene; Dr. John H. Stokes, syphilographer of the Mayo Clinic; Dr. Frankwood Williams, Director of the National Association of Mental Hygiene; Dr. W. S. Rankin, State Health Officer of North Carolina, and formerly President of the American Public Health Association; Dr. John Dill Robertson, former Health Officer of Chicago; Dr. John R. McDowell, Director of Health for the Lake Division, American Red Cross; Dr. John R. McMullen, U. S. Public Health Service; and Miss Frances Brink, Director of the National Organization for Public Health Nursing.

There are one million drug addicts in the United States according to estimates prepared by a committee appointed by the Secretary of the Treasury to investigate the use of drugs in the country. The report further states that only from 10 to 25 per cent of the quantity of drugs imported is actually needed to supply the demands of legitimate medical purposes. Much of the distribution of the drugs is through "underground" channels.

Public drinking fountains of the "bubble" variety in which the spurt of water is less than two inches have been banned in Cleveland by Health Commissioner H. C. Rockwood. Fountains with insufficient pressure to force the water two inches or more are a serious health menace and assist in spreading communicable disease, declares the commissioner.

Almost twice as many men as women die from tuberculosis in New York City, according to statistics set forth by Godias J. Drolet in *The Journal of Industrial Hygiene* compiled from the *Bulletin* of the New York Tuberculosis Association. From 63.1 per cent the male death rate per 100,000 from this disease has decreased to 59 per cent in 1920. The greater prevalence of the disease among men is ascribed to overwork and unhygienic workshops. Since 1917 when women entered industry in great numbers there has been a noticeable increase in the female death rate.

Announcement is contained in *Paris Médical* of an International Congress for the Protection of Infancy and Maternity called by the French League against Infant Mortality to be held in Paris, July 6-8, 1922.

Maryland now has a Children's Code Commission appointed by the Governor to codify the existing laws concerning children. The commission is to submit its report to the next session of the legislature. Members of the commission are: Judge Carroll T. Bond, chairman; Judge Morris A. Soper, Judge T. J. C. Williams of the Juvenile Court; Judge Jacob Mosen; George L. Jones of the Henry Watson Aid Society, Mrs. Charles E. Ellicott, chairman of the League of Women Voters; Miss Aimee Guggenheimer; and Miss Lavinia Engle.

That a state has a right to determine the amount of conservation of its natural resources and may exert its power to the fullest extent to discourage their waste was the decision handed down by the U. S. Supreme Court in the case of the State of Wyoming versus the gas carbon black producers. The State of Wyoming passed an act which prohibits as wasteful the burning and consumption of natural gas for its products without fully and actually applying and utilizing its heat for other manufacturing and domestic purposes. Of a possible 33 to 45 lbs. of carbon to be obtained from 1,000 cubic feet of natural gas, it was shown that the companies operating these gas wells obtained only 1.75 lbs. of carbon per 1,000 cubic feet of gas. Less than 5 per cent efficiency was considered highly wasteful.—Frederic Dannerth, in *Chem. Met. Eng.*, 25.104 (1921).

The Barrick Publishing Company, the J. C. Nichols Investment Company, and the Drivers National Bank of Kansas City gave life insurance policies to their employees as Christmas presents. The Barrick Publishing Company gave a \$1,000 dollar policy to each employee. The amounts of the policies given by the other companies varied with the term of service ranging from \$500 to \$2,000.

Free baths are being installed in every new public school building under construction in Baltimore as well as in all old ones which are being renovated. The baths with an attendant always in charge are open to the public as well as to the pupils.

The motion picture can be of great assistance in vocational education is the view J. J. O'Brien, President of the South Bend Lathe Works, takes in an article in December *Visual Education*. Films of various trades shown to boys in the sixth, seventh and eighth grades will enable them to choose the right occupation and avoid future industrial maladjustments, he believes.

A speech clinic for the special treatment of speech defects in ex-service men was established at the U. S. Public Health Service Hospital, No. 37, Waukesha, Wis., in January, 1920. Dr. Smiley Blanton of the University of Wisconsin organized the clinic and is in charge of its work. All the cases are under the supervision of a neuropsychiatrist and two psychologists, experienced in speech reeducation.

A Children's Bureau has been established as one of the divisions of the Pennsylvania Department of Public Welfare with headquarters at Harrisburg. Dr. Ellen C. Potter, formerly director of the Division of Child Health of the Pennsylvania State Board of Health, has been appointed in charge of the Children's Bureau. The Department of Public Welfare created by the 1921 legislature takes the place of the Board of Public Charities, the Commission on Lunacy, and the Prison Labor Commission. Dr. John M. Baldy is commissioner of the new department.

Governor General Leonard Wood has started an intensive campaign to improve health conditions in the Philippines. Circulars setting forth the causes of various diseases and methods of stamping them out have been posted throughout the islands. Four necessities for better living conditions in the Philippines mentioned by Governor General Wood were: More hospitals; more dispensaries; better distribution of medicines; additional nurses.

Two hundred two school children were enrolled in the speech-correction

classes at Omaha, Neb., during 1921. Of the 129 with phonetic defects, 49 were cured, 13 improved 75 per cent, 33 improved 50 per cent, 22 improved from 10 to 25 per cent, and the remaining 12 dropped out or moved away. Of the 73 stutterers enrolled in the classes, 27 were cured, 16 improved 75 per cent, 16 improved 50 per cent, and of the remaining 14, 10 to 25 per cent showed improvement. The average cost for each case was \$7.23.

A list of 221 titles of moving pictures on health is on file at the Bureau of Public Health Information, Health Service, New York County Chapter, American Red Cross, 598 Madison Ave. The Bureau will be glad to answer requests for information from health officials and workers about all kinds of health films.

Any health motion pictures available in New York City can be shown to any interested group through the offices of Edward Stuart, A. R. C., or E. G. Routzahn, chairman of Health Education and Publicity, of the American Public Health Association.

The death of two patients following treatment by chiropractors has caused the Chief Medical Examiner of New York City to issue a statement to all physicians that where death follows the treatment of persons by an unlicensed practitioner and there is reasonable ground to believe that such treatment contributed to the condition causing death, the medical examiner shall be immediately notified in order that an investigation may be made. The cases which prompted such a step were those of David Lebish, who died in St. Mark's Hospital, New York, from a ruptured appendix following treatment by a chiropractor and that of a man who died from blood poisoning after several chiropractors failed to recognize the nature of his malady.

The story of modern science is being told in popular terms by Prof. J. Arthur Thomson in "The Outline

of Science," which is being published serially by a London publisher. The book is an attempt in simple language to trace the development of the latest accepted scientific ideas on life and the universe. George Newnes, Ltd., Southampton Street, Strand, is the publisher.

The International Board of the Rockefeller Foundation has accepted an invitation to cooperate in the reorganization of public health activities of the Philippine Islands, and will lend the services of certain members of its staff as consultants to the Island officials. The Board will assist in coordinating health activities into a department of health, in developing the medical school of the University of the Philippines, and will provide post-graduate instruction in public health. Fellowships for advanced study in the United States will be offered and training of public health nurses will be established. Dr. Victor G. Heiser, Director for the East of the International Health Board, and formerly Director of Health for the Philippine Islands, will assist in carrying out the program.

The Indiana State Board of Health has established a new division known as the Housing Division. W. F. Sharpe, architect, is director, and is assisted by Albert E. Wert. Among the duties of the division are to make tenement house surveys and to pass upon plans and specifications made by architects of hotels, lodging houses and tenements. This is the fourteenth division attached to the Indiana Board of Health.

## Energy Requirements Studied

The *Boston Medical and Surgical Journal*, March 3, 1921, publishes a study of the energy requirements of girls from 12 to 17 years of age, from the Nutrition Laboratory of the Carnegie Institution of Washington. The laboratory has for one of its major problems the determination of the basal metabolism of the human from birth to old age. That of adults is affected independently by at least four factors—sex, wage, height and age. There is a distinct increase in metabolism, with increasing weight and height, and there is a distinct though slight decrease with increasing age.

## Cooperative Educational Work in Virginia

A note from the Cooperative Education Association of Richmond, Va., says that there are over 1,300 Community Leagues in the state, with a membership of more than forty thousand. The previous year they raised over \$200,000 for local improvement. They organized, among other things, a "Better Health Month" during which time each League planned to hold special health meetings on subjects of community interest, such as the sanitation of school toilets, safe drinking water, health rules, school health leagues, and other factors conducive to health, such as ventilation, etc.

## Evolution in Tuberculosis Treatment

A consideration of the historical background of present-day methods of tuberculosis treatment emphasizes the progress made and places the credit where it belongs—to the discrimination of early medical men who observed and measured results and the gradual development of a successful regime which could be universally applied. Tuberculosis is one disorder which has been made the subject of consistent study and

persistent socio-medical effort and it is one disease in whose death rate there is a marked and steady decline.

The following quotations are taken from *Medical Inquiries and Observations* by Benjamin Rush, M.D., published in 1809:

Doctor Latimer of Wilmington had been long afflicted with a cough and an occasional haemoptysis. He entered into the American army as a surgeon, and served in that capacity till near the end of the war; during which time he was perfectly free from all pulmonary disease. The spitting of blood returned soon after he settled in private practice. To remedy this complaint, he had recourse to a low diet, but finding it ineffectual, he partook liberally of the usual diet of healthy men, and he now enjoys a perfect exemption from it.

In regulating the diet of consumptive patients, I conceive it to be as necessary to feel the pulse, as it is in determining when and in what quantity to draw blood. Where inflammatory diathesis prevails, a vegetable diet is certainly proper; but where the patient has escaped, or passed this stage of the disease, I believe a vegetable diet alone to be injurious; and am sure a moderate quantity of animal food may be taken with advantage.

Doctor Way of Wilmington informed me, that a certain Abner Cloud, who was reduced so low by a pulmonary consumption as to be beyond all relief from medicine, was so much relieved by sleeping in the open air, and by the usual toils of building a hut, and improving a farm, in the unsettled parts of a new country in Pennsylvania, that he thought him in a fair way of a perfect recovery.

## Reduction in Tuberculosis

A NOTE of encouragement appears in Volume II, No. 3, of the *Statistical Bulletin* of the Metropolitan Life Insurance Company showing a remarkable decline in the prevalence of tuberculosis during the past decade. "These reductions," says the statistician, "are greatest at those age divisions of life when the tuberculosis death rate is highest, where it creates the heavy and social damage in terms of broken and dependent families and where it re-

moves wage earners from industrial life at a time when productive effort counts for most." The mortality rate in 1919 and 1920 for white males between twenty-five and forty years of age was about one-half the rate for 1911 and 1912. Reductions appear in other age groups among females, though to a lesser extent. The report concludes that "it has been possible for all community forces working together to modify the environmental and perhaps also the hereditary factors in tuberculosis as to reduce very materially the number of lives formerly lost to society on account of this disease."

## School Inspection in Belgium

Announcements recently made concerning the medical inspection in schools in Belgium state that while provision was made for inspection in 1914, on account of the war it was not carried out except in large cities. Government regulations of March 25, 1921, order medical inspection in all public and nursery schools and in private schools subsidized by the Government. The law prescribes, among other things, that children be examined upon entering school and at least once during each school year.

## Collection of Dust in Factories

The problem of dust in a factory may be accompanied by serious consequences. Insanitary conditions, waste, and inefficiency may result from unintelligent handling. Careful collection and attention to cleanliness will lessen the compensation liability, reduce fire insurance, and minimize the loss through sickness. An article of March 1, 1921, in *Factory* discusses the methods of removing dust, the various appliances through which air can be conveyed.

Dust is divided into that which is floating and that which is settled. An explanation is made of the various ways of removing each variety under different conditions. There is also a discussion of the merits of the various dust removing systems.

# Deodol

is an efficient and economical antiseptic, germicide and deodorant for use in surgery, gynecology and general sanitation. It represents a 50% solution of Cresol U. S. P. combined with saponifying agents.

Deodol added to water in any proportion makes a clear solution. It is non-irritating and non-destructive to tissues, will not corrode instruments or injure rubber, and does not stain. Deodol is practically non-toxic when used in the correct dilutions.

### A New Work on Industrial Psychology

A recent book on industrial psychology by Bernard Muscio deals largely with the contributions of psychology to the art of industrial management in a clear and convincing way. The author believes that industrial accidents caused by fatigue are comparable to typhoid fever caused by impure drinking water. The fatigue element in one case should be eliminated just as the impurities in the other.

In a discussion of the application of scientific principles of selection, the author believes they are not practicable or just in the case of skilled men, but he sees no reason why they should not be applied to children.

The concluding chapter gives a clear cut analysis of the common opposition of labor to scientific management, motion study, and task setting. Mr. Muscio sympathizes with the worker's point of view, but believes that a change from haphazard to scientific methods should be made.

### Treatise on Functional Nervous Disease

The object of "Functional Nerve Disease," a book recently issued by H. Crichton Miller, A.M., M.D., is to present in an epitome of war experiences for the practitioner a concise picture of the functional neuroses of war time in such a manner that "he may be able to apprehend the outstanding lessons taught by the experience of the great war in this department of medicine."

The volume consists of twelve chapters written by ten medical officers who have had experience in treating war neuroses. The editor calls attention to the fact that necessarily there will be found divergencies, repetitions, and even apparent contradictions in these various chapters, for which reason Chapter XII consists of a summary by William McDougall, in which

the main points of agreement of these various authors are stressed.

It appears to the reviewer that a medical practitioner unfamiliar with the neuroses would be likely to be confused somewhat by the arrangement of the material. This arrangement is, of course, unavoidable because of the selective type of subjects chosen by the various authors. The chapter upon differential diagnosis, while short, contains material of considerable value. Four chapters are devoted to the treatment of these disorders. One deals with the physical treatment, one with suggestion and persuasion, one with institutional management, and one with the management of the individual.

The volume may be recommended as one of great interest, affording, as it does, an opportunity for obtaining the viewpoints of several representative English neurologists. Especially interesting, in view of the very stubborn resistance, some years back, of the English neurologists to the philosophies of Freud, is the more or less general acceptance of the conception of repression, regression, unconscious mental conflict, and complexes. It may be said that some care is exercised in stressing the fact that the teaching of this book "does not require readers either to pervert wholly the meaning of the words sex and sexual, or to see the origin of neurosis in a very hypothetical sexuality of infancy."

Much of the subject matter deals with types of reactions with which the American physician has become familiar in recent years. As a single volume the book does not fulfill the requirements of clearly defining and describing war neuroses for the general practitioners.

Oxford University Press, New York, 1920.

### The Hysteria of Lady Macbeth

The tragedy of Lady Macbeth is discussed in a recent contribution by Isadore H. Corfat, M.D., in a short contribution which the author char-

acterizes as "a study in applied abnormal psychology and its object is to lay bare the fundamental mental mechanisms in one of the most prominent and interesting of artistic literary creations. The interpretation given by the author, namely, that Lady Macbeth is an accurate example of hysteria, is of some interest. He introduces his analysis of the problem of Lady Macbeth with a short dissertation upon the subconscious mental processes, the relations of somnambulism and hysteria, and psycho-analysis.

If this volume is intended for readers who are familiar with the modern trend of psychology the brief explanation contained in the first few chapters will suffice to render the subject matter relative to the hysteria of Lady Macbeth intelligible. Under this condition it would hardly seem necessary to present the introductory chapters at all. If, on the other hand, the contribution is intended to reach a more general reading public, it is doubtful if a clear conception will be obtained of this very interesting presentation.

Moffet, Yard & Co., New York.

### Medical Supplies Asked for Russia

Chairman Kahn of the Military Affairs Committee has introduced into the House of Representatives a resolution for turning over to the American Relief Administration the surplus medical supplies of the Army, to the value of \$4,000,000. Medical and hospital supplies in most localities of Russia are reported as entirely exhausted. With 50 per cent of the children in some sections suffering with malaria, there is not even quinin available for their treatment. According to the report of Mr. Hoover, the American Relief Administration is feeding 1,400,000 children.

## Barnard Girls Become More Robust

Barnard girls are getting more robust. They are less nervous than they used to be. Provost William T. Brewster, Acting Dean of Barnard during the recent absence of Dean Gildersleeve, emphasized in his report the fact that much better attendance at recitations and lectures than in previous years was now the rule.

Dr. G. Alsop, the college physician, and Professor Agnes Wayman, head of the department of physical education, both amplify the statement, and say that the health of the students has been in an unusually satisfactory condition during the past year. The periodical examinations show very encouraging gains in health.

Barnard freshmen and sophomores are required to take three periods a week in the physical education department work. Two of these must be gymnastic work; the other may be dancing, basketball, swimming or baseball. The gymnasium work may be corrective, remedial or otherwise, depending upon the girl's rating.

Two periods a week are required of juniors and seniors, and this is elective work. They may choose anything they are physically fitted to do.

The majority of the girls, however, devote four or five periods a week to work of the department, which is easily explained by the fact that it ranges from swimming and dancing through the field of sports to actual gymnasium work.

Barnard students are thoroughly examined in all respects at the beginning and end of the freshman year and at the end of the senior year. These are full physical examinations. The girls show marked gains from the work, says Professor Wayman, and the gain is shown not only in the change of figure, strength tests, expansion, girths, etc., but in actual health, lack of absence from classes and increased ability to study.

Professor Wayman produced an armful of shoes of strictly orthopedic last, and of various makes, which she said were all good.

"I tell them that if they will wear sensible shoes all day they may punish their feet with any kind of silly slippers for a little while at night," she said. Girls with foot defects are given special training in groups and shown how to use their feet and made to do corrective exercises with them. The exercises are definitely prescribed and progressive improvement recorded.

## Pan American Conference of Women

Miss Grace Abbot and Miss Mary Anderson of Chicago will lead the discussions on child welfare and women in industry at the Pan-American conference of women to be held during the convention of the League of Women Voters in Baltimore next April.

## Study Conduct in Health Examinations

Mental and departmental tests should be perfected as a part of health examinations for children, according to a statement of Dr. C. W. East in connection with an account of the State Fair Better Babies Conference of Illinois. Many parents object to having such grades as "over timid" or "resistant" given to children who, they insist, "are not timid at home," overlooking the fact that the child's attitude toward strangers is the point on which he is being scored. The September issue of *Illinois Health News* brings out the connection between the child's unsocial tendencies and the health and happiness of his later life. The only corrective is early mental hygiene.

## Ariston Gelatine Desserts

6 Pounds  
One or  
Assorted  
Flavors

Vanilla, Orange, Lemon,  
Pineapple, Grape, Cherry,  
Coffee, Strawberry, Rasp-  
berry or Loganberry.

You may have:

Or the plain powder, without flavor or color, at one cent less per pound.

The Flavors are pure fruit juices, made a part of the goods in the process of manufacture.

In preparing to serve, you have only to add water. The flavor is then always the same, of uniform strength.

Ariston Jelly Powders are Quality Foods—carefully made, of the very finest grade of pure gelatine.

Your test of the quality lies in the wholesome odor arising when hot water is poured upon Ariston powder. Make any comparison you choose, and be your own judge.

## Gorgas Memorial Institute a World Benefaction

To Extend the Work of Disease Prevention for the Benefit of Our Own and Future Generations

By W. C. BRAISTED, REAR ADMIRAL, U. S. N. (RETIRED), WASHINGTON, D. C.

FORMERLY men memorialized their heroes in stone, with the result that the monuments of the world are for the most part retrospective, representing some peak of past achievement, but exerting no vital force of inspiration or restraint except as they are reinterpreted by successive generations. And yet, if civilization is to carry on, it is through uninterrupted cumulative achievement; and the most enduring memorial to any man is the provision of the means by which to perpetuate his work. Especially when a humanitarian achievement has been made possible by the unusual skill or the clear vision of one man does such perpetuation seem desirable. As this applies to the work of General Gorgas, he may well be considered as the personification of the public health era and the plan of the Gorgas Memorial Institute in Panama a truly representative enterprise. Established in a country unhappily known as the pest hole of the Tropics, which by his efforts was transformed into one of the healthiest places on the face of the globe, the Institute will afford opportunities complete in every detail for trained research men and scientists from all over the world to work together upon the common problem of how best to prevent and eradicate disease.

Anyone who has seen the old Panama at the time of the abandonment of the work of the first canal, involving so much wasted energy, life, and

money, with its abandoned equipment and the evidences of unsuccessful labor, and the thousands of unknown and unnumbered graves of its workers, cannot help but be struck with

Bronze bust of General William C. Gorgas, made from life by P. Bryant Baker, sculptor, Boston, which will be placed at the entrance of the Memorial Building in Panama.

the present aspect of Panama, its splendid sanitation, its beautiful cities, its fine hospitals, and the magnificent accomplishment of the completion of the work of the canal, making it one of the most beautiful and salubrious spots in the world.

The accomplishment of this great

work and the sanitary regeneration of Panama are due to the efforts of the late William C. Gorgas, United States Army. To his efforts more than to any other agency the success of this work must be accredited. His earlier work in the southern states and the West Indies, particularly Cuba, his later efforts in Ecuador and Peru, and his projected work in Africa, give one an idea of the vast field of splendid endeavor which he accomplished and would have continued had his life been prolonged. His reputation has gone forth to all the world, and he is loved and revered in every household. Perhaps no single life has ever made possible so much for the good and well being of humanity as has that of General Gorgas.

Many types of memorials were considered to do honor to this great man, but I feel sure that the establishment of this memorial, The Institute for Research in Tropical Diseases and the Study of Preventive Medicine, carrying with it not only a permanent monument to his memory, but one that will continue his work and be of greatest value to the welfare of the entire world, will be considered the ideal commemorative effort. Panama, situated in the heart of the Tropics and in the midst of the Central and South American States which offer a splendid field of work of this kind, would seem to be the ideal location furnishing a wealth of material for the institution which is brought into existence.

Design of the proposed Gorgas Memorial Institute to be erected at Panama City. (From the *Bulletin of the Pan-American Union*.)

The honor for the conception of this idea and of bringing it into actual existence must be given to Dr. Belisario Porras, the President of the Republic of Panama. It was owing to his efforts and those associated with him, such as the Hon. Joseph Lefevre, the representative of the Panaman Government in Washington, that a Provisional Board was established to begin and carry on this work. Deep interest was evinced by all who have been approached on the subject in every part of the world, and especially by the Presidents and representatives of the Central and South American Republics, to whom the project was made known largely through the efforts of Dr. Franklin Martin, who visits these countries from time to time in the interest of the American College of Surgeons.

The preliminary plans of organization and control have been completed and the Gorgas Memorial Institute comes now to the attention of the public as a great and practical humanitarian movement, now making its appeal for support to the minds and hearts of the people. Dr. Richard P. Strong, director of the Harvard University School of Tropical Medicine, has been chosen as scientific director. Associated with Dr. Strong on the Board of Scientific Di-

rectors are: Dr. C. C. Bass, Director, Laboratory Clinical Medicine, Tulane University, New Orleans; Dr. W. G. MacCallum, Professor of Pathology, Johns Hopkins University, Baltimore; Dr. W. G. McCoy, Director, Hygienic Laboratory, U. S. Public Health Service, Washington; Lieut.-Col. J. F. Siler, Assistant, Division of Sanitation, U. S. Army, Washington; Rear Admiral E. R. Stitt, Surgeon General, U. S. Navy, Washington; Dr. E. E. Tyzzer, Professor of Comparative Pathology, Bussey Institute, Boston.

Executive officers are: Rear Admiral W. C. Braisted (retired), President of the Board of Directors; E. J. Stellwagen (President of the Union Trust Company), Treasurer; Arthur F. Robbins, Executive Secretary.

The Advisory Council, of which Secretary of State Charles Evans Hughes is a member, consists of the diplomatic representatives of practically all tropical countries, as well as a number of eminent physicians and surgeons and health officers, representing the leading medical, surgical, and public health associations of the United States.

The personnel of the Council includes such men as: Charles Evans Hughes, Secretary of State, U. S. A.; J. E. Lefevre, Chargé d'Affaires, Re-

public of Panama; Señor Don Beltran Mathieu, Minister of Chili; Tomas A. Le Breton, Ambassador of Argentina; Señor Don Federico Alfonso Pezet, Ambassador of Peru; Augusto Cochran de Alencar, Ambassador of Brazil; Dr. Carlos Manuel de Cespedes, Minister of Cuba; Dr. Jacobo Varela, Minister of Uruguay; Dr. Julio Bianchi, Minister of Guatemala; Licdo. Emilio C. Joubert, Minister, Dominican Republic; Albert Blanchet, Minister of Haiti; Señor Emilio Chamorro, Minister of Nicaragua; Señor Adolpho Ballivian, Minister of Bolivia; Dr. John S. South, Minister to Republic of Panama; Brig. Gen. Charles E. Sawyer, U. S. Army Medical Corps; Brig. Gen. Robert E. Noble, U. S. Army, Medical Museum and Library; Rear Admiral Cary Grayson, Washington, U. S. Navy; Dr. A. J. McLaughlin, Assistant Surgeon General, U. S. Public Health Service; Dr. Carlos Chagas, Oswaldo Cruz Institute, Brazil; Dr. Henry S. Wellcome, Washington; Lieut. Gen. Sir John Goodwin, Whitehall, London, England, Director, Army Medical Services; Sir John Y. S. MacAlister, London, England, Head of the Royal Society of Medicine; Sir Patrick Manson, London, England, London School Tropical Medicine; William K. R. Simpson, London, England, President.

Some of the original incorporators of the Gorgas Memorial Institute at Panama. (From left to right) Dr. Richard P. Strong, Harvard University; Surgeon General W. C. Braisted, U. S. N. (Retired); Hon. J. E. Lefevre, representing the Republic of Panama; Surgeon General Merritt W. Ireland, U. S. Army; Dr. Franklin H. Martin; Judge John Bassett Moore.

Royal School of Tropical Medicine.

Associations represented on the Advisory Council are the American Medical Association, American College of Surgeons, American Public Health Association, American Society of Tropical Medicine, Southern Medical Association, and Southern Surgical Association.

The Panamanian Advisory Council consists of: Colonel Henry C. Fisher, Health Officer, Canal Zone, Panama; J. B. Duncan, Secretary, Public Instruction, Panama; Dr. Lewis B. Bates, Chief of Health Laboratory, Panama Canal, Panama; Major E. A. Boccock, Superintendent, Santo Tomas Hospital, Panama.

#### Location in Tropics Advantage

The subject of tropical medicine has been one of deep interest to all medical minds in every part of the world. While much has been done in our largest and best educational institutions to endeavor to carry on research work and to acquire knowledge of tropical diseases, and a great deal has been accomplished by many special institutions and departments, such as the London and Liverpool Schools of Tropical Medicine, and the work of such institutions as Harvard, Johns Hopkins, the University of California, and many other organizations of this kind, nevertheless all this work has been limited and hampered by the dearth of material for such study and research and on account of the distance

of these institutions from the tropical centers. The Tropics, so prolific in vegetation of all kinds, seem equally fertile in the development of all types and kinds of dread diseases, which tend to make them unsuited and impossible of habitation until careful sanitation makes them safe. Among the diseases which suggest themselves as possible to study in this institution are malaria, yellow fever, plague, dengue, human trypanosomiasis, beriberi, pellagra, leprosy, the various helminthic infections, cholera, the various mycoses, the myiases, etc. Added to these are the many unknown and undiscovered banes of existence which remain to be found out and to be made innocuous.

It is to be remembered that the dangers of tropical diseases is not confined to the Tropics alone, but on account of world intercourse are being constantly carried to the non-tropical countries, endangering their health and well being. The corps of men especially skilled in tropical and preventive medicine may be expected to exert from this Institute the control of diseases in a way that never was dreamed of in days gone by. The splendid chain of hospitals already built and building in Panama, which are the equal of any in the world, furnish opportunity for the care, isolation and treatment, and study of any persons that may be found. It is expected that research workers everywhere will take advantage of the

privileges offered at this institution and that scholarships will be developed in the great educational institutions which will enable deserving young men of high attainments to acquire through the Gorgas Memorial Institute a thorough grounding in this work of prevention that means so much to the well being and happiness of peoples everywhere.

The opportunities for training will be supplemented by the Gorgas School of Sanitation, established in response to the united demands of the Health Officers of the Southern States, which will deal particularly with study and experimentation having to do with health problems peculiar to the Southern States, the primary object being to develop sanitary engineers, county health workers, and public health nurses. The scientific program of the Institute is tremendously practical, the organization is well planned, the ends no less than the elevation of health standards and the promotion of scientific sanitation everywhere. One can readily picture the possibility of extending beyond the confines of Panama the overcoming of tropical fatality and the rise again (in the words of Gorgas) of great tropical empires, "such as Egypt and Babylon, and that from the period of Panamanian sanitation will be dated the beginning of the great white civilization in these parts." Indeed, it may well presage the rise of a sanitary era of "health to all people, in all lands."

Dr. Belisario Porras, president of the Republic of Panama, and member of the board of directors, who initiated this movement. (Harris & Ewing photograph.)

# Popular Medical Misconceptions

**M**EDICINE is not an occult art and it is not in unusual conditions or spectacular cases that the practising physician must look to his laurels, but in the conscientious routine care of the most common disease conditions. Medical practitioners and investigators stand in the unique position of continually trying to prevent the very things by which they earn their livelihood. The idea of prevention permeates medical practice: the patient with a common cold or sore throat is urged to keep away from his neighbors; those with severe infectious diseases are quarantined. Every effort toward early diagnosis of obscure conditions is an effort at prevention either of complications in the individual or in the case of certain diseases, like tuberculosis, prevention of the spread of the disease to others. No program of disease prevention is possible by paternal or bureaucratic methods. To be successful, the prevention idea must spread to the people and be democratic in spirit as well as in application. In everyday life pretty much the same idea of cooperative effort is necessary for any kind of practice.

Yet despite fully trained and well intentioned physicians, we continue to have a high death rate from preventable causes. Why do so many defects go unremedied, and so many patients present themselves for treatment only in the last stages of disease? Personally, we believe the reason to lie in certain well grounded but popular medical misconceptions. Having not the slightest conception of the complexity of the human organism at work, it is commonly believed that a disease condition is confined to one offending organ and that some drug—any drug, perhaps—should be able to cure it. It is not generally understood that a spasm of pain may be referred to a remote organ and that any train of symptoms would necessarily call for some study and investigation on the part of the examining physician; but the credulous public, so ready to trust anything except exact science, still thinks that a pain in the back means kidney disease; in the stomach, indigestion; that headache is headache simply, and that for any of these conditions a prescription should afford instant relief. Not only that, but they pass medical advice around and, even at this late day, peddle prescriptions!

It is pair and disturbed activities

that people resent. They tolerate at great length the most persistent signs of disease, and their symptoms, self-interpreted, are often neglected till remedy becomes an impossibility. It is most disconcerting to observe how prone people are to interpret their own symptoms. "When a young man has indigestion he thinks he has heart disease; when an old man has heart disease, he calls it indigestion," and the judgment of neither is of any value in his own case.

It is necessary, then, in the interest of early treatment, for a patient to understand that persistent headaches, chronic "indigestion," gradual loss in weight, or increasing lassitude are subjects for study, not guesswork. Confidence in the physician consulted is the next essential. Getting at the facts in any case requires the utmost frankness on the part of both physician and patient. The remedy will usually involve some change of habit or occupation not readily undertaken and impossible to enforce without the fullest cooperation on the part of the patient. In these days of psychic fads one scarcely needs to argue the importance of mental *rapport* between the physician and his patient. The difference between the attitude of enthusiastic support of the prescribed measures and mental resistance, or even the passive acceptance of a physical handicap, may mark the difference between hopelessness and a safe outcome in treatment.

It is partly for this reason and partly because without a knowledge of the physical and mental make-up of the patient the physician cannot acquire an adequate background of the disease picture that the habit of "shopping around" is so pernicious. A patient, to be understood, must be subjected to thorough initial study and periodical "checking up." Even if the patient who shops around is always lucky in his choice of a physician, he has at least the added worry and expense of repeated examinations and faces the danger of delayed diagnosis, and it is the "shopper" on whom the cults and charlatans thrive. Sooner or later it is the "shopper" who resorts to self-medication. It is important to remember that many people take poisonous drugs with more or less regularity under the mistaken notion that they are beneficial because they relieve some symptoms.

Perhaps it is too much to expect the people to seek rational guidance

in health matters until they are more inclined to assign to health conditions the importance they deserve. Almost any material thing seems more urgent in its appeal than a health venture. There is nothing dramatic or appealing about preventive measures self-applied. Habits of procrastination delay the "stitch in time." The working girl will cut down on lunches to buy furbelows; the housewife with mistaken sense of economy will disturb the balance of the family ration. The resultant lassitude or chronic headache remains unquestioned and stands fair to be accepted as inevitable. Somehow people must come to feel that physical well being is an indispensable asset and its lapse an affair of immediate concern. Minor complaints, as inefficiency, irritability, lack of endurance, must be investigated as to their physiological basis. Such an attitude, coupled with a generalized knowledge of certain outstanding signs in the more common disorders, should serve as the best health insurance available.

The University of Iowa made a recent inquiry as to popular notions concerning psychology which brought out the most astounding contradiction of ideas. The insurance companies tell us that certain of the degenerative diseases claim more and more of our population. Does the public know what are the danger signals in Bright's disease, for instance? Or the unfavorable signs in the high blood pressure series? Or when so-called "indigestion" calls for a surgeon instead of castor oil? We propose to discuss a series of disease pictures of this character for the benefit of the interested public, for if preventive medicine is to become effectual, the physician must be called before he is needed to sign the death certificate.

## The Interpretation of Symptoms

When people cease to think they can interpret their own symptoms, the sale of patent medicines will fall off. One reason for the popularity of many patent medicines lies in their methods of appeal. The standard picture of the poor crippled man with back bent, one hand pressed to sore spot, and the other holding the bottle of kidney remedy, is quite prophetic of the good the poor sufferer may expect from the medicine. It is not only prophetic; it is much more pathetic. Although this symbol is fortunately becoming almost a thing of the past, the picture still holds an object lesson in the peculiar psychological reaction of patients to various symptoms.

Nothing is more difficult to the trained diagnostician than the interpretation of the complex symptomatology offered by even a simple "case," but the sufferer from a pain in his back immediately hitches the pain to his kidneys,—organs which he knows are also located in the back. The medical man knows how rarely serious diseases of the kidneys are associated with backache. The advertising proprietor knows it also; he knows likewise that the fellow with the pain in his back usually thinks he has kidney trouble. So the sufferer buys the medicine, takes it, the pain disappears,—and, behold, he is cured of serious kidney trouble!

This illustration serves excellently as an example of the manner in which the average patient waits for the appearance of pain before he is willing to consider himself sick. The onset of symptoms of all except very acute kidney diseases is insidious and does not call the attention of the individual to any abnormality. He will not consider or even admit the possibility that getting up at night to urinate is a sign of serious kidney disorder. Yet this slightly disturbing symptom is frequently the first and only sign of trouble and, if noticed early, may make possible the prevention of much more serious trouble. Osler wrote many years ago on the advantages of finding a trace of albumin and a few casts in the urine of some men over fifty years old, meaning that such early revelation of renal disorder often enables the prevention of later complications. But it is very difficult to make the average busy man realize that it is distinctly abnormal to have to get up at night, so he waits for the occurrence of pain somewhere before it occurs to him to consult his physician. To the average layman pain in the back belongs to the kidney; how can it be, he may say, that a pain in the head could come from disease of an organ so far removed from the head? Therefore he proceeds to wait until some pain becomes severe enough to cause him to ask for relief. Even then he will doubt the diagnosis, perhaps even discredit the ability of the physician who suggests the necessity of a thorough examination for such a simple thing as a pain in the head. The pain in the back is relieved by kidney remedies; why not the pain in the head by headache powders?

### Guess Work is Tragic

Pulmonary tuberculosis is another disease standing out as a glaring example of the difficulty or unwilling-

ness on the part of those affected properly to interpret the initial symptoms. The tragedy of advanced pulmonary tuberculosis could in many instances be averted if the patient knew a little more or a little less of the relative importance of various symptoms. As in trouble with the kidneys, the patient is prone to overlook what seem to be patent signs of trouble until the arrival of pleural pain and overwhelming weakness causes him to seek medical aid. Physicians are repeatedly called upon to examine tuberculous patients who give absolutely no history of a cough, but who nevertheless cough more or less continuously while giving their history. They seek aid for the pain, but they persistently ignore a long-continued decline in weight, night sweats, a little hack in the morning, lassitude, and general run-downness; but pain—in this particular disease— or, finally, seeing blood, wakes them up, often too late, to the realization that they are sick.

The real history of most cases of pulmonary tuberculosis probably does not begin with anything very definite, except in the comparatively rare instances of early hemorrhage. An early profuse hemorrhage is more often a life-saver than a killer. Calling attention in the most dramatic way to illness, the appearance of hemorrhage frightens the patient into seeking a physician. Yet hemorrhage in tuberculosis certainly causes fewer deaths than neglect of the less vivid, but more insidious symptoms of weakness, loss of weight, or the slight morning' hack. It is perfectly easy for the physician to interpret the undramatic drab symptoms which paint a black picture; but before seeking medical aid the average individual seems to require a more vivid display of color, or a more rapid course than most diseases present.

One other disease may be used to compare the dramatic with prosaic symptoms. Excepting the large group of diabetics who are discovered by life insurance examinations, most diabetics do not consult the physician for the early symptoms which really paint the definite disease picture. Increased appetite, increased thirst, excessive urination to the average patient do not appear as particularly alarming symptoms, but in most instances they mean a disease which, if controlled early, may save life and if allowed to run on may destroy life. It is most difficult to understand why so many normal minded individuals are willing to go along with an array of abnormalities, whose presence must be no-

ticed. They will wait for the development of a boil,—which hurts,—for impaired vision,—which interferes with a peculiarly susceptible organ,—the eye; or for pains in an arteriosclerotic limb before they stop long enough to inquire the reason for the earlier complaints. That in most instances such neglect is due to carelessness is evidenced by the histories of such patients. They do not complain of the increased thirst or appetite, and often on questioning are not even ready to admit their existence. They date their story from the onset of pain; and when attention is called to the fact that a tremendous loss of weight is practically impossible with such a short history they are still unready to acknowledge the long series of the other undramatic symptoms.

### Chicago Health Officer

DR. HERMAN N. BUNDESON  
Commissioner of Health, Chicago, Illinois

Dr. Herman N. Bundeson has been appointed Commissioner of Health of Chicago to succeed Dr. John Dill Robertson, who resigned in February. Dr. Bundeson is a graduate of the Northwestern University Medical School and of the United States Army Medical School at Washington, D. C.

He holds membership in the following societies: Chicago Medical Society, Illinois Medical Society, American Medical Association, Associated Military Surgeons. He is attending serologist of the Illinois Central Railway and a member of the Contagious Staff of the Illinois Masonic Hospital Association.

# National Health Council Achieves Unification Through Common Service Committee

## The Common Service Committee Serves as Coordinating Agent of Interests and Facilities

By DONALD B. ARMSTRONG, M.D., SECRETARY, COMMON SERVICE COMMITTEE, NATIONAL HEALTH COUNCIL, NEW YORK, N. Y.

FARSIGHTED health workers for many years have felt the need of a body to study the coordination of the activities of the voluntary national health organizations. Their efforts resulted finally, in the spring of 1920, in an investigation to determine what the possibilities in this direction might be. A preliminary conference was called by Dr. Livingston Farrand, then Chairman of the American Red Cross, at which the entire matter was fully discussed, and a special health coordination study was launched with the financial aid of the American Red Cross.

On December 10, 1920, following the report of the coordination study, a number of leading voluntary health organizations met in Washington and formed the National Health Council, practically as at present constituted. The membership of the Council in-

*In the past the criticism that voluntary health agencies duplicated one another's studies and efforts might have been made with some degree of justice, but, with the establishment of the National Health Council, that criticism can no longer with any fairness be applied.*

*The National Health Council maintains offices in the Penn Terminal Building, New York City, where under the administration of a Common Service Committee, are located a joint library service, an account service, an editorial, purchase and sales, letter, shipping, and miscellaneous mechanical services.*

cludes three types of members, direct, indirect, and conference members.

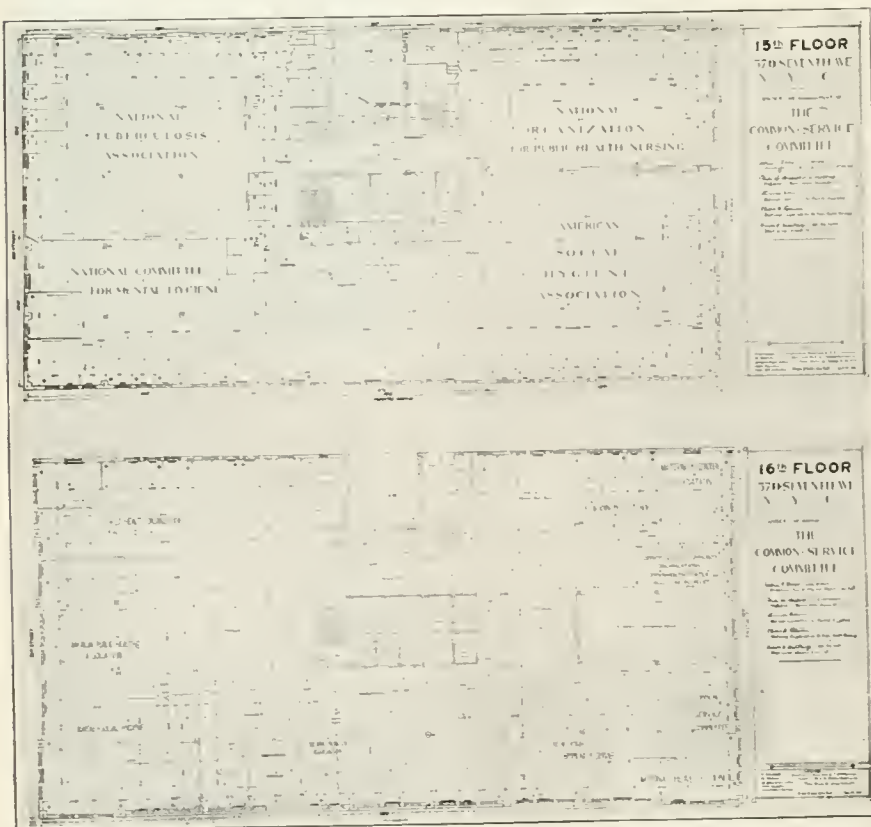

Direct members now numbering ten include the American Public Health Association, American Red Cross, American Social Hygiene Association, American Society for the Control of Cancer, Conference of State and Provincial Health Authorities of North America, Council on Health and Public Instruction of the American Medical Association, National Child Health Council, National Committee for Mental Hygiene, National Organization for Public Health Nursing, and the National Tuberculosis Association.

Indirect members, affiliated through membership in the National Child Health Council, three in number, include the American Child Hygiene Association, Child Health Organization of America, and the National Child Labor Committee.

The United States Public Health Service is at present the sole conference member of the National Health Council.

The Council is governed in the following way. Each of the member organizations appoints a representative and alternate to represent it at the quarterly meetings of the Council. Special committees have been appointed or otherwise created, the most important being the Business Committee, the Membership Committee, and the Common Service Committee. The last is technically an independent committee organized to administer the common activities and office quarters of the member organizations located in New York City.

The Council is financed by dues from its member organizations and by contributions from Foundations, other organizations, and individuals. The budget for 1921, contributed chiefly by the American Red Cross, was approximately \$21,000. The plans of the Council have crystalized in the past year to some degree and the activities tentatively and experimentally initiated have met with a fair degree of success, seemingly justifying a somewhat greater budget for 1922.

Floor plans showing the location of the agencies taking part in the joint office arrangement.

Conference room of the National Health Council.

The National Health Council offers certain services, primarily for the benefit of its constituent members. Grouped under four main heads they include the information bureau; the bureau of special temporary services; projected services; and joint conference groups.

The information bureau publishes the *Monthly Digest* of current health news, thus making it possible for each organization to learn intimately what new projects are being planned, the results of current projects that are nearing completion, and the special fields of organization or other activities entered into by the members with whom they are not in constant direct contact.

In the field of legislative information the bureau issues from the Washington office bi-weekly bulletins on Federal health legislation. The Washington office also issues a series of reports on government bureaus. These reports attempt to give accurate pictures of the organization of the government bureaus, especially in regard to their bearing on health work, their interrelation and correlation with each other, and the significance of this interrelation to national health work. At Washington, also, in cooperation with the United States Public Health Service and other government bureaus, there is being developed a series of bulletins on state health legislation, covering those states having legislative sessions in the current year.

Maintaining a current calendar of conference dates is another service the information bureau offers. This is useful in avoiding conflict between important meetings and conferences in the health field.

In cooperation with the members of the Council the bureau undertakes certain special activities. A recent activity effectively completed was the launching of a Rotary Health Week from December 5-11, 1921. In cooperation with the request of the International Association of Rotary Clubs of America, the National Health Council suggested a program of activities, sponsored jointly by the Council and the Rotarians, which involved the launching of a National Health Week. Besides offering suggestions the National Health Council stimulated the newspapers and the efforts of its members in attaining maximum educational value for the campaign.

Another special activity of the information bureau is the lecture course on the organization and services of

health agencies which was given in the Conference Room of the National Health Council in New York City. The course is designed to give the members of council staffs a picture of the functions of health agencies, how they may cooperate, and how their services may be secured. The New York office has established an employment service, interviews applicants for positions in health work, and suggests to organizations personnel to fill their needs.

#### Special Service Bureau

The "bureau" of special temporary services has evolved out of needs which have arisen, and is really a child of circumstance that has thrived during the period of stress. It is now well beyond the stage where there need be question as to its mortality. The American Public Health Association Health Institute, one of the major activities in connection with the Semi-Centennial of the American Public Health Association, was managed by the staff of the National Health Council through its bureau of special temporary services. The institute was operated entirely by the Council, the burden being thus removed from one of its members during this time when the Fiftieth Annual Meeting required all the attention of the American Public Health Association.

Another activity of this type was the Health Highway on which the voluntary health agencies who exhibited at the health show in New York were housed.

The Council has undertaken certain studies to consider ways and means for more effective correlating of nurs-

The joint library serving all the organizations which are members of the Council or which share in the offices.

Hall and information desk on the fifteenth floor.

ing supervision and the nursing service of certain organizations. Suggestions for the conservation of time and energy have come from this study.

The third service that the Council offers is that of recently initiated or projected services. A field service has been suggested by several member organizations aiming at the development of new channels of service, the coordination of field activities, and the offering of consultation and advice to local communities on organization, and other matters. Plans are now maturing for the launching of such a service, primarily for the benefit of the members of the National Health Council, to be underwritten by those members who wish to take advantage of such a cooperative activity.

Another projected service which has grown out of New York joint office interstaff group conferences is the statistical service. We may illustrate here how this type of conference group functions and how it may develop out of a discussion group into a functioning service. The statistical conference group is composed of the statisticians of the member organizations. The staff statisticians are guided in their conferences in a measure by the Executive Officer of the Council and certain outstanding authorities in the statistical field. Recently two organizations in the field of health, one a member of the Council, felt the need of statistical service, but their requirements did not justify full time workers. On the recommendation of the interstaff conference group which was asked for suggestions regarding ways and means, the Council recommended the pooling of the needs and statistical facilities of

these organizations. To meet these needs a statistician will probably be engaged by the National Health Council, and the time and expense prorated among the organizations purchasing this service.

Still another service, which is projected and which is developing in much the same manner as is the statistical service, is the exhibits' plan of the Council. Certain organizations in the field of health and welfare, including official boards of health, have appealed to the Council for assistance in the matter of plans for educational exhibits. It has been suggested that the Council develop this service of exhibit planning and administration further. This is now under consideration by an exhibit conference group.

A further service, recommended to the Council by an American Public

Health Association committee, concerns the health motion picture question. This committee recommended that the Council take over its functions and develop them along certain suggested lines. This recommendation, no doubt, reflects the recognition of the fact that the Council is in an advantageous position to develop information, standards, and methods in this field. Similar committees are also studying the fields of health plays and health publications.

The members of Council staffs who are interested in certain special activities, particularly those with which the Common Service Committee is concerned in the joint renting project, meet periodically in conference for discussion of topics of mutual interest and for the formulation of plans for further effective coordination. An illustration of their methods was given in the previous section in the description of the evolution of the statistical conference group. Groups functioning in this manner are the conference group on publicity and education, which is developing in the fields of publications and publicity, exhibits, motion pictures, and health plays; the statistical conference group; conference group of business managers, which meets periodically to discuss questions important to those concerned chiefly with the business operations of the offices; conference group of secretaries; conference group of librarians; group interested in the health of employees; and joint recreation committee.

The Common Service Committee is the result of a pooling of certain interests by members of the National Health Council, who, while retaining

The shipping department of the Common Service Committee.

complete autonomy, have agreed to share certain facilities to the ends that service might be increased, the cost of operations reduced, and equipment brought within the reach of the group which would otherwise be too great a burden for any one organization. This Committee offers facilities, among which are joint library service, an account service, editorial service, service of purchase and sales, letter service, shipping service, and miscellaneous, special, mechanical services.

The Common Service Committee has also taken over the renting arrangement for the group of agencies now in the Penn Terminal Building. Cooperation between the various members is freely forthcoming. A notable example of this type of exchange may be seen in the recent American Public Health Association Semi-Centennial. Staffs were borrowed, facilities exchanged, and in general there was evident during this emergency a complete unity of purpose, regardless of organization interests.

Certain organizations not members of the National Health Council are participants in the joint renting arrangement. They are American Nurses Association, Bureau of Social Hygiene and Committee on Drug Addictions, Maternity Center Association, National League for Nursing Education, New York Diet Kitchen Association, United States Interdepartmental Social Hygiene Board (representative). Additional social agencies having office space are Circle for Negro Relief, Committee for Study of Community Organization, Commonwealth Center, Eugenics Record Office, New York Community Service, National Probation Association.

The plans of the Council for this year naturally involve a continuation of the services described above, most of which have developed satisfactorily during the Council's first year. It is also planned further to develop the projected services, a few of which have been described above, including the field service, statistical service, the studies of exhibits, motion pictures, etc.

Another activity in prospect is the development of health educational material. This has been suggested and outlined, and now awaits only the necessary staff and finances. A study of health educational material in foreign languages has also been urged and a tentative procedure sketched, but with the limited staff the Council thus far has had to yield to more immediate demands.

Still another activity, which has

Letter service department of the Common Service Committee.

been favorably considered, is the launching of a National Health Day. The experience with Rotary Health Week has made clear the fact that the Council in such undertakings with and for its members may count upon the enthusiastic support and cooperation of official and voluntary health organizations.

At the end of its first year, the Council surveys the land and finds a definite field for service. The Federal Government, together with the states, is the logical guardian of the nation's health. Certain activities in the field of health and preventive medicine are, however, of such a nature that experimentation and development can with advantage be carried on within the jurisdiction of private organizations, at least to a point where the experimental period is safely over.

With many voluntary agencies working in this field experimenting and testing out methods and materials, there is danger of overlapping and duplication. It is to reduce, in a measure, the chances for waste, and to enhance the opportunities for cooperative effort, that the Council enters into its second year of activity.

The officers of the National Health Council are as follows: Dr. Livingston Farrand, chairman; Dr. Lee K. Frankel, vice-chairman; Dr. S. F. Crumbine, recording secretary; Dr. William F. Snow, treasurer.

Common Service Committee consists of Dr. William F. Snow, chairman; Dr. Charles J. Hatfield, vice-chairman; Dr. Thomas W. Salmon; Mr. A. M. White; Dr. Donald B. Armstrong, secretary.

Direct members, their representatives, and alternates are: American Public Health Association, Lee K.

Frankel, representative, M. P. Ravenel, M.D., alternate; American Red Cross, Livingston Farrand, M.D., representative, W. Frank Persons, alternate; American Social Hygiene Association, William F. Snow, M.D., representative, Bascom Johnson, alternate; American Society for the Control of Cancer, Frank J. Osborne, representative, Howard C. Taylor, M.D., alternate; Conference of State and Provincial Health Authorities of America, S. J. Crumbine, M.D., representative, Arthur T. McCormack, M.D., alternate; Council on Health and Public Instruction of the American Medical Association, Watson Rankin, M.D., representative, Frederick R. Green, M.D., alternate; National Child Health Council, Philip Van Ingen, M.D., representative, Courtenay Dinwiddie, M.D., alternate; National Committee for Mental Hygiene, Frankwood E. Willams, M.D., representative, alternate to be appointed; National Organization for Public Health Nursing, Elizabeth Fox, R.N., representative, Anne A. Stevens, R.N., alternate; National Tuberculosis Association, Charles J. Hatfield, M.D., representative, James A. Miller, M.D., alternate.

United States Public Health Service, conference member, is represented by Surgeon General H. S. Cumming, with Surgeon George W. McCoy as alternate.

The staff of the National Health Council consists of Donald B. Armstrong, M.D., executive officer; Lawrence Marcus, executive assistant; James A. Tobey, Washington representative; Helen B. Eveline, secretary and assistant. T. C. Edwards is manager of the Common Service Committee.

# The Problem of the Working Mother

## Marriage and Motherhood Should Not Be Cause for Dismissal of Woman from Work

By A. LOUISE McILROY, M.D., D.Sc., PROFESSOR OF OBSTETRICS AND GYNECOLOGY, LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, UNIVERSITY OF LONDON

IN discussing the problem of the working mother, I draw a distinction between marriage and motherhood, and it is my intention to deal with the question mainly from the point of view of the working mother, whether married or single, who has in her work the complications of pregnancy and the care of the infant.

The question of marriage, although involving that of motherhood to a certain extent, affects only the private life of the individual, and should not concern the employer, either public or private. In the case of a man worker there is no inquiry into his domestic affairs. According to the Sex Disability Act a woman must not be penalized because of her sex or on marriage, and any employer dismissing a worker because of marriage is contravening this Act. We had a recent example of such an infringement of the law when the St. Pancras Council dismissed several of its women workers, one being a woman doctor, because of marriage. The action taken by such a public authority is an interference with the liberty of the individual, a liberty which has been won after a hard struggle by those men and women who believe in the equality of the sexes. Such an action must not be allowed to pass without a vigorous protest; otherwise it will stand as a precedent. Yet how many women's associations have taken up the question with a view to righting its injustice? It is one of the most important economic questions which concern women's work and until it is settled satisfactorily, women will have to continue as casual workers as they have done in the past. Now that many men lack the worldly goods with which to endow their wives, marriage is becoming more and more a partnership where the woman contributes her share of financial help by means of her working capacity, be it brain or hand.

When women have once enjoyed economic independence, it is with great reluctance that they relinquish it, nor is there in the majority of cases any necessity for doing so on marriage until the problem of motherhood arises as a complication.

*Since the economic urgency requires the presence of many women in industry and professions, the stand the British government has taken of dismissing a woman from service upon marriage is manifestly unjust and in contravention of the Sex Disability Act which states that a woman must not be penalized because of her sex or upon marriage.*

*The problem of the woman in industry is twofold, concerning itself alike with the effect of motherhood on woman's work, and the effect of her work on her health and that of the child. The gradation of work during pregnancy, the granting of leave, and a maternity endowment fund to which both the State and the parents contribute will solve in some measure the problem.*

In the government services, women are dismissed on marriage no matter how brilliant their individual record may be or how important their work is to the state. Women workers under the Home Office are dismissed, but the blow is softened by the gift of a dowry intended to ameliorate to a slight degree their new conditions of dependence. In all the government offices women are dismissed on marriage, and only single women are taken on for employment. With such an example before them it is small wonder that minor local authorities follow suit. The educational authorities are at present sitting on the fence and hold the threat of possible dismissal over their married staff who have served them faithfully during the stress of war.

Is there any sense of justice or fair play in a state which closes useful careers to women who may have spent years in making themselves of the greatest value to their work, and yet keeps in employment the weaklings among men? Is it due to colossal selfishness on the part of some

officials who appear content that a woman's sole energies which were directed towards the public good should on marriage be entirely absorbed for the use of one man?

Women do not want to be parasites, nor to hamper their men by increased expenditure. They want a degree of economic independence not only that they may afford to wait to mate with the man of their choice, but that they make marriage possible by contributing also to the house.

Equal work and equal pay is the demand of women, and as long as a woman does her work satisfactorily, her private life should be just as little the concern of her employer as that of a man. Women have yet to realize the power they have in the vote and that the solution of the problems dealing with women's work lies in their own hands.

The state makes celibacy and sterility compulsory among its women workers and thus it either loses their valuable work, or prevents the handing on of the capacity for good service to the next generation. If women were dismissed on marriage because of some supposed incapacity whereby their work suffered, there might be an element of reason in the matter; but when it is merely the opposition of a trade unionism among men who support their wives, to keep out those women who contribute as partners, one sees the narrow basis of it all. There is also a degree of opposition from single women who jealously guard the interests they have acquired by their individual exertions.

The state dismisses women on marriage, but it is not above taking advantage of the combined incomes of husband and wife in the income tax returns. It is a restraint on the marriages of those women who have private incomes or who earn them in professions where they continue as workers after marriage.

If women's work is to end upon marriage, then the prospect of marriage is the ruination of a woman's professional or industrial career, as she can never be more than a casual worker at the best. It is a question with many complications which cur-

tails the advancement of women in all branches of work, because marriage to most normally constituted women will present attractions which outweigh any career.

### Evils of Such Dismissals

The dismissal of women on marriage leads to several evils. It delays marriage for men who cannot afford the upkeep of two people, and therefore encourages prostitution. It invites partnership without the ceremony of marriage. A single woman who procures abortion may continue at work while another woman on respectable marriage is liable to dismissal. From the economic point of view women with the prospect of marriage before them may be tempted to accept work at a lower wage than men and so undermine the value of men's work.

In places where only single women are employed there is no inducement for them to become skilled, and such women therefore remain at heart casual workers. Also, since many efficient women do marry and relinquish their careers the state suffers itself to be served by beginners and those with little experience. Such a condition of affairs has a serious aspect in professions such as medicine.

The celibate pioneers of women's work renounced everything for the good of their cause. They were group workers and personal sacrifice but added a joy to the work. But now that their work is more firmly established, women with but little knowledge of the first struggle demand the right to live under normal conditions.

### The Working Woman's Problem

The problem of the working woman who expects to be a mother or who has the cares of a family on her shoulders is much more complicated in its solution. From the standpoint of an obstetric specialist, my concern is mainly with the health of the expectant mother and the care of the child. Pregnancy renders the average woman temporarily incapacitated for her work and must be faced boldly in the hope that some working solution may be found.

Public opinion must be educated to the fact that the state can neither afford to reduce its production of children nor dispense with its enormous number of highly skilled women workers. The present attitude of looking upon motherhood as a crime which causes dismissal from employment, just as drunkenness in a man, must be abandoned.

Motherhood is the highest function

a woman can fulfil and it should rightly be a profession in itself; but it is as a rule so badly paid that it cannot be regarded as a lucrative profession. It is an ideal condition that the mother should make the home and the father concern himself with its financial support. But since the war, financial stress is so great that the maintenance of proper home conditions is in many cases a great anxiety and burden.

Among women of the better classes pregnancy can as a rule be arranged for and the care of the children deputed to skilled attendants. A woman can be just as good a mother although she may leave the bathing and combing of the children to others. Her method of rearing her family is her own concern provided she keeps in line with general public opinion and legislation.

Criticism is too frequently passed on a woman who, by training her mind, is enabled to keep up a high intellectual and spiritual atmosphere in her home, and who turns out sons and daughters of more value to the state than those of a household drudge who never thinks beyond the clothing and feeding of her offspring.

I do not for a moment advocate the neglect of a mother's duties in the home, far from it, but I do appeal for perfect liberty for such a woman to conduct her family affairs on the lines which she and her husband consider best. Among the better classes the good offices of more leisured relations are often obtainable. The maiden aunt, the modern substitute for the fairy godmother, deserves a place among the angels who guard the destinies of little children.

Home duties for women are diminishing rapidly owing to labor saving devices which in time will leave the housewife nothing to do. The char-woman is being replaced by the vacuum cleaner and the electric washer.

The problem of motherhood is greatest among the industrial classes and the war has had much to do in accentuating its difficulties.

The war has had three main influences upon woman's work. During the national danger the needs of the country were put before those of the home or individual. Women nobly responded to the call of the state and took up industrial work without hesitation. No doubt the condition of working at high pressure would have told eventually upon the health of the nation if it had been prolonged, but for the time, from a woman's economic standpoint, the conditions were almost ideal. Women felt they were

wanted as workers and the demand was almost greater than the supply.

Now conditions are changed and women are dismissed on the least pretext. It is not surprising that marriage and motherhood are used as an excuse. But the war has shown forcibly the economic value of women's work and it was the recognition of this fact that gave the final impetus to the granting of the franchise.

The fact that women accomplished so much during the war, and in many cases without much previous training, has brought about a wonderful increase of confidence in themselves and in the work of other women. No longer is a woman's work criticised by her own sex because she is a woman attempting man's work; she is an individual standing on her own personal merits. No longer is her sex a handicap in other women's eyes.

Economic stress and financial difficulties are at present facing the country. Women must again come forward and help. It is no longer a disgrace for a woman to earn her own living or to maintain her family by her work. In many cases the father is disabled or cannot find employment and the main burden of the support of the family falls on the woman. The strain and anxiety involved in making ends meet may be just bearable if a woman can retain her profession or trade, and the financial advantage will make all the difference in the happiness and harmony of the home. The children will be enabled to have a better start in life. But the question is, can a woman serve the state by the reproduction of children and at the same time retain her employment or must she be debarred from handing on the legacy of her trained intellect to the future generation? It is well known that clever sons owe most to the clever mothers who have produced them.

There are two aspects to be considered: (1) What effect has the function of motherhood upon woman's work; and (2) What effect has work upon the health of the mother and her offspring?

### Effect of Pregnancy on Work

The creative energy in man and woman is used up to a great extent in work, especially in brain work. The best work of the world is done during the reproductive period of life and provides the creative force that brings the fresh ideas for invention and research. It is the sex force which stimulates and renders the worker keen.

Celibacy is therefore possible in in-

dividuals when this force is used in directions other than in the actual reproduction of offspring. Where it is not so used there is over sex stimulation with bad results. When used for work there is less for reproduction and vice versa. Pregnancy temporarily diminishes the market value of women's work because in women the reproductive force when exercised is much more specialized than in men; although there is a degree of variation in the individual.

Dismissal of the expectant mother by the employers is brought about for the reason that risks are greater to the worker during pregnancy. If work is compulsorily abandoned for a time, it is difficult to regain owing to the keen competition at the present moment.

If pregnancy is to be avoided it entails various consequences: (1) celibacy on the part of some of the best intellectual and expert workers among women; (2) free love without the ceremony of marriage; (3) the use of contraceptive methods; and (4) the induction of criminal abortion.

Contraceptive appliances should only be used on the advice of the medical profession and for medical reasons. They should not be allowed to be advised or supplied by the laity. Their use is against the teaching of the churches. They undermine the health and morals of those who use them, and they will lead to the downfall of the Empire as they have done in the past histories of other great nations. Although they are advocated for the reduction in numbers of the casual and unemployable classes, in practice they are not possible for such classes. They are used by the middle classes because of financial strain, the increased love of luxury, and to avoid parental responsibility.

In women where the sex interest is stimulated by marriage harmful results follow the denial of the greater maternal instinct. They lead to unlimited sex indulgence and their use cannot be restricted to the married, owing to the present widespread knowledge of their so-called advantages. They turn a normal physiological act which should be spontaneous and the outcome of affection and impulse into a premeditated physical indulgence. Those members of the medical profession who are concerned with the study of diseases of women are almost unanimous in their condemnation of contraceptive methods except on the advice of the medical practitioner.

The casual classes can be dimin-

ished only by improving their economic conditions and so enabling them to become members of the industrial classes; at the same time preventing the destruction of homes and families among the regular workers who are forced to sink under the economic stress and strain of unemployment. If women after the completion of their child-bearing were enabled to return to their special work, there would be a great decrease in the numbers which annually go to swell the ranks of the unemployed.

The casual classes have little incentive to control their offspring, for while a beneficent state takes over and cares for the drunken, mentally deficient, and those afflicted with venereal disease, at the same time it penalizes the worker by taxation and by the dismissal of the women who are bravely endeavoring to keep their homes respectable.

Women of the industrial classes endeavor to conceal pregnancy for fear of dismissal; they therefore frequently suffer from ailments which, if unattended, have bad results upon their future health and that of their children.

#### Effect of Work on Mother

Motherhood is a normal physiological function and should be the natural right of every woman, but civilization makes it in many cases abnormal. It is advisable that the expectant mother should remain under her accustomed conditions as nearly as possible, provided they have no harmful effects upon her or her future offspring. Work, if not harmful in its effects, should be continued. The same conditions as to diet and exercise should be advised as before pregnancy occurred.

Many women just maintain a fair balance of health with difficulty, but if pregnancy is added that balance may be upset. Such women must be carefully watched and all symptoms dealt with, provision being made for modified work or in some cases complete rest.

The state, by the provision of a Ministry of Health with its care of the expectant mother and infant welfare, has at last shown itself alive to the value of the potential mother and her unborn child. An enormous machinery has been set in motion to guard the mother during pregnancy, labor, and convalescence, and to reduce the high infant mortality. The special branch of medicine known as obstetrics has made almost more rapid strides than any other during

the last quarter of a century, and much is being done to find out by clinical observation and laboratory research methods which will tend to secure as healthy a future generation as possible.

The endowment of motherhood has now become a national question, and the one endeavor of all right-minded thinkers is to obtain for a mother every security during pregnancy and childbirth by granting permanent assistance when necessary to enable her to be relieved of all anxiety and worry.

In large industrial centers facilities for the care of the expectant mother are given by the ante-natal clinics of the maternity hospitals, also care during confinement, and post-natal advice. The children can be kept under observation at the infant clinics and welfare centers. In this way much of the chronic ill health due to pregnancy is diminished and the infant mortality reduced both before and after birth. But, if an expectant mother, owing to economic pressure, endeavors to conceal her condition and tries to do heavy work, it is not surprising that her health suffers and that pregnancy is often interrupted.

It has been advocated by a number of obstetricians that pregnancy should be notifiable in order to secure medical supervision for the expectant mother. But notification has several objections and the education of public opinion as to the advantages gained by attendance at a maternity clinic or seeking the advice of a medical practitioner, is of greater value. Legislation is not only unnecessary but frequently harmful in laying down rules which cannot apply to all cases.

The problem of the treatment of those infant diseases due to venereal disease, rickets and mental deficiency, will find a considerable part of its solution in the care of the expectant mother.

Motherhood must be looked upon as work for the state and provision must be made for the mother while undertaking that work, just as a soldier is provided for while defending his country.

#### Gradation of Work Advisable

Provision for motherhood must go upon two lines. As pregnancy means a temporary dislocation of the work, employers must be induced to make allowance for it by grading the work according to the capacity of the worker. A woman working in a light and cheerful factory with graded

work is under much better conditions than one who on dismissal has to take to "charing" with its long irregular hours and often unhealthy surroundings. Work involving the lifting of heavy weights is dangerous, but light manual work, especially where sitting is possible, is permissible up to the end of pregnancy. Such work was found to be satisfactory among pregnant women in munition factories, as Dr. Rhoda Adams of Leeds can testify.

Leave should be granted for pregnancy if advised by the medical inspector, just as one month's leave is laid down at present for the confinement. But there should be no fixed period of absence enforced as women vary so much in their capacity for work.

The child should be given an opportunity for being fed with the mother's milk by the provision of welfare centers in the factories where the mother can attend at regular intervals.

Many municipal authorities, while dismissing married women from their employment, are perfectly willing to act as wet nurses to their children rather than encourage employment with facilities for nursing and thus

enable the mother to rear her child or at least pay for its milk supply when breast feeding is impossible. This alone would mean a great saving in the rates.

### Maternity Endowment Fund

In order that women may retain their work and return to it when pregnancy is over, the employer must in no way be penalized, otherwise all endeavors to solve the problem of the working mother will be useless. Equal pay for equal work is the universal demand, but if the work suffers from some incapacity on the part of the worker, less remuneration must be accepted. For this reason, therefore, the reduced remuneration for the graded work of the expectant mother must be supplemented by a maternity endowment fund. To this fund the state ought to contribute a proportion, the rest being found by the parents of the expected child. It should be in the nature of an insurance fund for maternity leave, and the amount of benefit should vary with the individual's requirements and the time taken from work. Maternity leave should not be looked upon as a dis-

ability, such as sickness leave, but as the fulfilling of a natural function, on completion of which the worker may return to normal conditions and employment.

It has been used as an objection that endowment schemes will encourage illegitimacy, but this can be denied. No scheme for the treatment of the effects of immorality will increase immorality itself but rather tends to diminish it. The unmarried mother, by the provision of hostels where she can live and retain her baby, and at the same time earn a respectable livelihood in a factory or shop, has a much less chance of joining the prostitute class than one who has been compelled to live in idleness in a workhouse, and associate with those who are hardened to immorality if not to crime.

More education as to the protection of girls and the respect due to motherhood should be given to boys and men. Is there any indecency in such education in an age where the dissemination of advice as to the prophylactic treatment of venereal diseases is advised by a large section of the community?

## The Sewerage System of Caracas, Venezuela

### An Enterprise of Interest from Both the Sanitary and the Engineering Viewpoints

BY OUR SPECIAL LATIN-AMERICA CORRESPONDENT

THE installation of the sewage disposal system of the city of Caracas, Venezuela, presents many interesting features both from the sanitary and the engineering viewpoints. Situated on the side of a mountain at an altitude of 972 meters above sea level, the city inclines at a varying gradient to the Rio Guaire which skirts a valley floor. The slope on which the city is located is broken sharply to varying depths by gullies which enter the river basin at right angles. These are called quebradoes and contain little streams carrying storm water and sewage. The buildings for the most part are constructed of stone or brick with tile roofs and the streets are paved with stone and concrete. The houses with their paved patios are closely placed and during the rainy season the storm water runoff is extremely rapid. At such times the quebradoes are well flushed but in the dry season, December to March inclusive, they dry up and become

merely trickles of household sewage.

Here then, was a city of 80,000 persons, the capitol of an extensive country, rich in natural resources,

Note the sewer passing under bridges and opening for storm water. House drains enter sewer from either side.

which from its foundation in 1512 to 1919 had not even contemplated a well thought out sewage system. A few abortive efforts had been made,

the covering of the quebradoes with an arched roof of brick, had been attempted in several places and a short trunk line sewer paralleling the river had been begun, but no complete plan on scientific lines had been made.

After various preliminary studies, the plan at present being put into force was made and was authorized on June 13, 1919. The project, which is highly original because of the peculiarities of the local terrain, as pointed out above, has been modified slightly to meet the knowledge gained as the work went forward. As a result, the Ministerio de Obras Publicas de Venezuela, under whose direction the construction is being carried out, has been able to do the work economically and well. The project, which was designed by Dr. German Jimenez, owes its genesis to the inspiration of General Juan Vicente Gomez, the President-Elect of the Republic and to the genius of Dr. L. G. Chacin Itriago, the Director de Sanidad Nacional who realized that the

Discharge gates for flood water peak loads. Where rain falls at times at the rate of three inches per hour, the overflow discharge is very rapid.

public water supply of Caracas could never be safe for human consumption until the leaky, uncharted system of drains, which at present intercommunicate with the water delivery system, had been abolished.

As a matter of fact, practically all of the old system will be entirely scrapped as soon as the new one is completed because all previous work was badly planned as to location, type, side, and gradient and without a proper conception of the sewerage system as a whole.

After collecting, compiling and analyzing all the meager data available and making a careful topographic and hydrographic study of the drainage area, it was decided to lay the sewers in pairs in the beds of the quebradoes and to carry these to the trunk line which paralleled the Rio Guaire, into which the sewage eventually empties. The entire system will cost, when completed, about fifteen million dollars in gold, but for the present a sewage disposal plant must be foregone on account of lack of funds. Dr. Chacin Itriago has prohibited the irrigation of vegetables with Rio Guaire water and those grown below the city may not be brought into or offered for sale in Caracas. An efficient purification plant is a part of his ultimate plans, however.

Sanitary sewage and ordinary street and roof run-off will be carried

by the sewers, which are constructed of reinforced concrete. Run-off from outside the city and direct rainfall into the quebradoes themselves will be handled by the old stream bed lying between the sewers. Excess loads of storm water will be discharged by swing gates opening into this space. Of course these waters will contain

a certain admixture of sewage but inasmuch as the rains at such times are intense—sometimes as high as three inches per hour—the overflow discharge will be very rapid and from a sanitary viewpoint, without danger.

The sewers on cross section present a rectangle superimposed on a trapezium having a semi-circular bottom. This permits rapid run off with minimum sewage load, the semi-circular portion carrying ordinary dry-season city discharge, the trapezium the residential and factorage sewage, and the rectangle, flood waters. There are manholes every one hundred meters and at curves and changes in gradient. Inspection, air and light openings are provided at twenty meter intervals in the smaller sewers, and traps, screens or gratings guard all flood water entrances against trash and stones. Dumps are located at points convenient for removing sand and mud. In one situation, where the trunk sewer crosses the Rio Caroata, a two-cylinder siphon 1x21 meters is inserted.

The best materials are being used throughout and good workmanship is insured by continuous, careful inspection. When completed (and the work is being rapidly pushed) Caracas will have one of the best sewage disposal systems in South America with a consequent improvement of its public health, as the health situation was chiefly an engineering problem.

# Teaching Health Through Pictures

BY CHARLES F. POWLISON, GENERAL SECRETARY, NATIONAL CHILD WELFARE ASSOCIATION, NEW YORK CITY

**H**EALTH cannot be forced from without; it must be fostered from within. All the health regulations in the world will avail but little in lowering a city's death rate unless its citizens are taught how to live healthfully. Fifty years ago, boards of health did little but fumigate, quarantine, and investigate complaints of "nuisances." Nowadays, an increasingly large part of their activities consists in educational work.

The same thing is true in the schools. We are beginning to realize that physiology is far less important than hygiene,—that it avails a boy nothing to recite the names of all the bones in his body, if he cannot stand correctly, and that right habits in eating are far more useful than exact knowledge of the digestive processes.

But the teacher's problem is not merely to impart information concerning hygiene. Her task is to arouse her pupils' interest, to enlist their wills,—as one public health worker had said, to awaken a "hygienic conscience" within them. Our children must be given a real love of health, a real desire for health habits, a real sense of responsibility and pride in

NOTE:—The pictures illustrating this article are reproductions of educational panels prepared by the National Child Welfare Association, 70 Fifth Avenue, New York, and are taken from over four hundred subjects relating to the physical, mental, and moral development of babies and children. The panels are 17 x 28 inches in size, lithographed on very heavy, durable paper, hand-colored and eyeletted for hanging. They are arranged in series of five to twenty-five panels. Bulletins with prices will be sent free by the Association. Their handbook illustrates all of the panels and also contains much helpful information on Child Welfare.

There was a crooked man  
Who walked a crooked mile;  
But I, when I go walking,  
Don't walk in crooked style.  
I keep my chin and stomach in  
And hold my chest up higher,  
And step along so straight and strong,  
And never, never tire.

acquiring and keeping the best of health.

## The Visual Appeal

Now how shall the teacher reach and arouse the wills of her pupils? How shall she make them desire health?

The old fashioned method was that of the birch rod. But birch rods, hickory sticks and rulers are no longer considered legitimate means of arousing a thirst for knowledge. They were discarded in favor of less vigorous methods, and we of the older generation were taught almost exclusively through our ears, by dint of endless repetition, recitation, and exhortation by pupils and teachers.

It remained for a wiser generation to learn that the shortest road to the will is not through the ear, but through the eye. Instruction too often "goes in one ear and out the other," but, as someone has remarked, it has never been accused of "going in one eye and out the other." Thus it is that visual education is at last taking its rightful place as a means of

answering this question by the issuance of a steadily increasing series of panels on such topics as prenatal care, prevention of tuberculosis, hygiene for school children, physical care of babies and children, the Modern Health Crusade, foods and health, aids for the nutrition clinic, Mother Goose health rhymes, prevention of orthopedic defects, and Babes in Healthland.

As the titles indicate, many of these series are intended for use among ignorant mothers and fathers. The success of a modern school is not complete until it has enlisted the interest and cooperation of the

arousing the desires and the activities of both children and adults.

How can the principle of visual education be used in imparting health habits?

For ten years past, the National Child Welfare Association has been

pupils' parents. In many schools, these panels are being used for talks and discussions in the Mothers' Club or Parent-Teacher Association. Sometimes they form the basis for an entire winter's program. Such a logically planned program must result in more interest, more intelligent understanding of the children's needs, and a heartier joining of hands between home and school.

In the baby clinic, milk depot, or infant welfare station, the panels, hung in the waiting room, are eagerly studied by the mothers, who, baby on arm, pass from one to another. Even without the simple wording, the picture carries its message and reinforces the words of doctor or nurse.

The public health nurse often takes a few panels on her rounds to drive

home her message, for these simple mothers have a touching faith in the printed word. Many nurses have lent panels to the local churches, libraries, granges, schools or community centers. Many a nurse and settlement worker will testify that she can make more impression upon a group of ignorant women in a half hour with the picture panels than in twice the time without them.

And as it is with the parents, so it is in far greater measure with the

children. In school-rooms all over the country, these educational picture-panels are proving their usefulness.

Many teachers have used the panels as subjects for the pupils' compositions. Others assign certain panels to selected pupils who read up on the subject and deliver brief lectures to their classmates. Still others merely hang up the panels, a fresh one each week, and let them speak for themselves.

The success of these methods is evidenced by letters from many teachers. A teacher from Jeffersonville, Ind., says, "Already the children have learned, 'There was a crooked man' and could you have seen them yesterday afternoon 'stepping straight and strong,' when we went for a hike, you would have rejoiced."

The wide applicability of the panels is shown by the fact that they are in use in twenty-four foreign countries and that Dr. Yamei Kin is translating them into Chinese for use in her native land.

At a recent exhibit at the Univer-

sity of Illinois, 2,000 school children, in relays, were instructed by means of these panels, and 3,500 students

man, after studying the panels long and with intense interest, said to the field worker in charge, "Say, lady, if they'd had them things when I was a boy, I'd been a better man."

He struck the keynote of the National Child Welfare Association's purpose,—so to educate and arouse the boys and girls of today that there may be better men and women tomorrow. Indifferent health conditions give way to an enlightened interest.

## Housing of Non-Family Women

A SURVEY of the housing of the non-family women in Chicago has recently been published by the Chicago Community Trust. Two college trained girls, new-comers in the city, were sent room hunting as prospective lodgers, investigators incognito. Newspaper ads and room rent signs were the bases of action. About one hundred rooms were visited and reported in each of the three districts selected for investigation. The loop district was not included. Some of the ads included hotels with thirty to fifty rooms, with better heating systems, a daily change of towels and other more businesslike administration perhaps than private rooms.

Details of the data compiled cannot be given here. On the North Side 90 per cent of the homes visited rented more than four bed rooms; on the South Side 65 per cent; and on the West Side 92 per cent. Only a few single rooms rented for less than seven dollars per week. Thirty-six per cent of the places on the North Side rented from five to eight

dollars per week, 71 per cent on the west, and 56 per cent on the South Side, where the best conditions seem to prevail. Twenty-six per cent of the baths reported for the South Side were used by more than six persons, 41 per cent on the North Side, and 52 per cent on the West Side. The sanitary condition of toilets, the ventilation, house privileges for the entertainment of guests, and the furnishings of the rooms are reported. The situation in institutional homes and residence homes was surveyed and reported. A list of room registries with the work or territory covered by each is given.

From the data collected specific conclusions and recommendations are made, among others that: Facilities in special boarding houses and residence clubs should be increased; inadequate provision is made for transients; a permanent council or conference on the housing of non-family women should be organized composed of the organizations interested in housing for women.

# An Indigenous Fish Used in Combating Malaria\*

In the Malarious Belt all Standing Water Must be Considered a Constant Menace

By H. H. HOWARD, M.D., INTERNATIONAL HEALTH BOARD, NEW YORK CITY

AS RAPIDLY as possible the program for testing the top feeding minnow as an agent of mosquito control was put into effect. Many water deposits were already stocked with minnows naturally, some in sufficient numbers for control, while in others fish had to be added. Water deposits were prepared for fish control by the removal of all debris and aquatic vegetation, and the edging of their shore lines. It was necessary to maintain this condition in the water deposits throughout the season to render the minnows effective as control agents. The following table shows the water deposits controlled by fish which were introduced in the numbers indicated. Those water deposits have naturally a sufficient number of fish for control do not appear in this list:

Water deposits	Number of fish introduced
56 ponds .....	3,184
1 creek .....	460
12 branches (tributaries of creeks) .....	2,105
27 ditches .....	4,764
16 pot holes .....	1,100
1 seepage area .....	85
1 spring .....	50
3 dipping vats .....	335
5 cisterns .....	134
3 wells .....	44
<b>125</b>	<b>12,221</b>

During the last half of the season of active mosquito breeding, in more than 90 per cent of all water deposits in the controlled area mosquito production was being satisfactorily and effectively controlled by the *Gambusia*. For a more detailed report of the operations in 1919 see "Use of the Top Minnow (*Gambusia Affinis*) as an Agent of Mosquito Control," by H. H. Howard, Report No. 7486 I. H. B.

In 1920 the same area was kept under control with methods similar to those employed in 1919, except that fish control was made our main dependence throughout the season and was extended to all classes of water deposits. During the season of 1920, in approximately 85 per cent of the water deposits where control was attempted, the top minnow was the sole agent employed, and in 10 per cent of those remaining, mosquito control was secured in part by the use of fish. The total estimated number of top minnows used for stocking purposes

during the season 1920 was 7,500. At the opening of the season 1920 it was found that, among the water deposits stocked with minnows in 1919, the fish had disappeared from 37 potholes. Ditches and branches which carry only storm water drying down to pools in dry weather, had retained the fish through the winter remarkably well, but it was necessary to redistribute and replenish the fish for the season of 1920 in a number of water deposits of this class. All running streams, ponds, borrow pits, dipping vats, springs, and other water deposits of a permanent nature retained the minnows throughout the winter 1919-1920, and in but few instances was it necessary to restock or add to the number of fish in these places.

At first the top minnows for stocking purposes in these experiments were secured mainly from those waters within the controlled area where there seemed to be an excessive number of fish. Later a pond was reserved for breeding purposes, and from this source a large proportion of the fish for control measures were obtained. The rapid increase of minnows in some of the waters stocked with them for control purposes furnished part of the supply, and from deposits outside the controlled area

it was possible at any time to supplement the stock of fish.

An ordinary bobbinet dip net was used for the capture of the top minnows. They were found to bear transportation for reasonable distances very well in water of air temperature. A five or ten gallon milk can has proved the most suitable vessel for such purpose. The female seem to bear transportation better than the male, and the mature fish better than the young. It was found that the *Gambusia* is easily bred in large numbers. Experience would suggest that, for breeding purposes, a large pond should be selected; the waters of the pond should be fairly clear and free from contamination; there should be extensive "shallows" at the margins of the pond to which the young fish may retreat and escape from the cannibalism of the adults. The spillway of the pond should have a fish guard of No. 14 or No. 16 gauge wire to prevent the escape of the young fish, which seem to have a very strong instinct to follow flowing water at every opportunity.

The recognized enemies of the *Gambusia* in the section of Mississippi where these experiments were conducted were the predacious fish—mainly the bass—and the black water snake. Neither of these, however,

No. 9. Mill ponds showing heavy aquatic growth, mainly floating primrose (*Jussiaea diffusa*). This is a very pernicious water growth, almost impossible to eradicate, which prevents the *Gambusia* from gaining access to the mosquito larvae. Its introduction into the waters of malarious sections should be prohibited.

\*Part I of this article was presented in the February issue of THE NATION'S HEALTH.

were ever a serious menace to the *Gambusia*, which, if other conditions were at all favorable, would thrive and multiply rapidly in the presence of either or both of these enemies.

### The Numbers Necessary

The number of top minnows necessary for the effective control of mosquito production will vary according to the nature of the water deposits, its shore line conditions, the available food supply, and the presence or absence of active predacious enemies to the fish. Probably the number of mosquitoes visiting the water for ovipositing may also be a determining factor. For practical purposes, and to obviate the necessity of attempting close calculations on uncertain grounds, the following procedure was adopted in the experiments that are being outlined:

Mosquito inspections were made every ten days. When the inspector discovered mosquito larvae in a water deposit under fish control, it proved safe to attribute their presence to one or both of two things—first, the insufficient number of fish, and second, the presence of too much vegetation and débris. The remedy consisted of increasing the number of fish or clearing away vegetation or débris, or both.

As a routine practice, 25 or 50 fish were used to stock a water deposit. A larger number than this was used where it was desired to bring mosquito production under control quickly. The proportion of males to females in the section referred to was 1 to 15 or 20. For this reason, investigations were made to insure the presence of two or more males where only 50 fish or less were used in

stocking isolated water deposits. The mature male *Gambusia* may be distinguished from the female by its smaller size and its long and flowing anal fin.

The following facts concerning the life history of the *Gambusia Affinis* are taken from Document No. 857, issued by the United States Bureau of Fisheries:

The *Gambusia Affinis* usually inhabits shallow, stagnant waters, whether fresh or brackish, and it thrives under conditions of relatively high temperature if the proper amount of food is available. It is a very hardy fish, adapting itself readily to many different natural conditions as well as to life in the aquarium. Its food consists largely of larvae of insects, but it feeds also upon a variety of other animal and plant substances. It sometimes eats its own kind, even its own offspring, especially in the restricted environment of an aquarium. One medium size female may destroy as many as 165 large mosquito larvae in a day. In the region of Beaufort, the fish produces its first brood of young for the season during the month of May and continues to breed . . . until as late as October. It may produce during a single season six or more broods, averaging forty young to the brood. . . . The young are delivered during the day, one, two, or three at a time. . . . Some of the individuals of the early broods of the season become sexually mature and breed small broods of young late in the season in which they themselves are born.

The observations made in the experiments already described coincide with the statements made by the author, Mr. Hildebrand, in the quotation given above.

In the consideration of the merits of the several measures most often employed for mosquito control, unquestionably drainage occupies first

place as regards efficiency and permanency of results. Moreover, it is likely that figures could be adduced to show that, in the majority of instances, it would be the most economical measure ultimately. It is not often possible, at the present stage of mosquito control in this country, however, to secure funds to meet the heavy initial cost of a comprehensive drainage program. It is the impossibility of attaining the ideal which has compelled the adoption in some instances of measures of control, the results of which are too often continued scarcely beyond the period of their application. Of such measures of control, oiling—the results of which are probably the most transient of all—has been considered the most effective under certain conditions, and has consequently been the most widely used. While it is not proposed to decry here the use of oil or to depreciate its value in meeting emergencies, yet it must be said that, with the price of oil high, very high labor cost for its distribution, and much preparation and maintenance of field conditions necessary for its successful use, it is only wise to give due consideration to promising less expensive and possibly more lasting measures of control. This is especially true when operations in large areas are contemplated.

Not only is oiling as a measure of mosquito control, expensive and very transient in its results, but its effectiveness is subject to extremely definite limitations which are too often lost sight of or disregarded.

In Reprint No. 260, *Public Health Reports*, Mr. J. A. Le Prince sets forth some of the limitations of oil as a control means, as follows:

It is not advisable to oil water when the film will not remain effective, as just before rain storms. During the rainy periods the value of oil is decreased. The ability of the larvae of mosquitoes to live under an oil film for an hour should be considered. Oil films will not penetrate a barrier of grass or move around similar obstructions. When such obstructions to the oil film occur on the water surface and are not removed, sufficient oil must be used to cover both the obstruction and the spaces between them. Wind will break up the oil film and transport all oil to one shore of the body of water.

In a large rural district with extensive mosquito breeding areas of every variety and condition, often these limitations alone may operate to the undoing of control operations by oiling. Consequently, the system of inspection and supervision necessary to prevent such a contingency

No. 10. The same mill ponds cleared of vegetation and their banks "edged" in preparation for fish control.

No. 11. "Bogue Chitto," the largest of the three streams in the District, at the normal water level. These streams are in their original channels, which are tortuous and winding, often containing brush, logs, and other debris which greatly impede their flow. They are subject to frequent "overflows" during heavy rains. During the autumn and early winter, when precipitation is lightest, their water level falls and they are without current. They usually contain large numbers of the *Gambusia* which control mosquito breeding except in places rendered inaccessible to them by debris.

must be constant and thorough, and will be correspondingly costly.

Some of the following apparent advantages of fish control as compared with oiling may be of interest:

Where the top minnow (*Gambusia Affinis*) is indigenous, or where it may be introduced and bred in large numbers, its use as an agent for mosquito control is attended with no further cost than that incurred for its capture and transportation.

The petroleum mixture, which is commonly used for mosquito control, costs more than twenty cents per gallon, and the cost of its application is correspondingly high.

One stocking of minnows will suffice for an indefinite period in water deposits of a permanent nature, and as a rule for a much longer period than a single oiling in every instance.

Oil must be applied every seven to ten days in dry weather, and oftener in windy and rainy weather.

While methods for the preparation of bodies of water for oil control and fish control are much the same, it was very evident during our control experiments in the seasons of 1919-1920 that top minnows will maintain effective mosquito control in the presence of debris and vegetation, which

would render oil ineffective. Thus both the cost of preparation for oiling and the cost of maintenance may be higher than in fish control.

The effectiveness of the oil film is quickly destroyed by winds, rain, waves—natural phenomena of frequent occurrence. These have practically no effect upon the minnow as a control agent.

A general stocking of the waters of any mosquito infested section with the *Gambusia* results in not only immediate, but material and enduring reduction in mosquito production.

It seems evident that this means of mosquito control, even if other measures fail or are discontinued, will continue indefinitely to operate against mosquito breeding unless disease, natural enemies, or some unforeseen cause should lead to the extermination of the top minnow.

As has been remarked before, oil as a control measure is transient in results, and to be effective must be regularly and continuously practised. If, in any instance, it is discontinued, probably no lasting benefits as regards mosquito control will come from its previous use.

The intelligent and effective use of top minnows as an agent of mosquito

control requires practically no technical training or expert knowledge on the part of those who would use them for this purpose.

Oiling, to be done effectively, requires considerable technical knowledge and training.

A careful examination and study of conditions in the controlled area during the last year of our experiment (1920), and an analysis of our cost data, enables us to estimate that the use of the *Gambusia* as an agent of mosquito control has made possible a saving of 50 per cent to 60 per cent in the cost of control, with the additional advantage that we are leaving behind us, as our work closes, an agent of control which will continue to function and hold mosquito production more or less in check indefinitely. We may further state that we are by no means certain that the control of mosquito production would have been possible without the use of the top minnow, because of the presence in the area of more than 80 stock ponds which were essential for the convenience of the people and could not be drained or filled, and which would have been rendered unfit for stock had they been oiled. Experiments with oiling in several of the ponds which were not in use at the time rather tended to show that, had the use of oil been permissible in the stock ponds, it would not have been effective in controlling mosquito production, mainly because of the drifting of the oil film by the wind.

While we have carefully analyzed the data collected in 1918 and in the two subsequent years as to the number of water deposits in which mosquito production was being partly or wholly controlled by the *Gambusia* under conditions of natural distribution, it being indigenous to the section, we are not prepared to even estimate the measure of mosquito control resulting from the activities of the *Gambusia* under these conditions. Probably no proper valuation can be made of the *Gambusia* as a controlling factor in mosquito production where the fish is indigenous, unless it were possible to observe mosquito production for a period of years with the *Gambusia* present in natural distribution, and then to eliminate the fish and note the changes which might occur in mosquito production through a period of several years.

We were able, however, to ascertain, during the observation period of 1918 and before any artificial measures for mosquito control were put into effect, that in approximately 35 per cent of the water deposits in the

district, mosquito production was being nearly or wholly controlled by the *Gambusia* under conditions of natural distribution. In sections where artificial ponds, which are usually inaccessible to the *Gambusia*, unless the fish is purposely placed in them, are less numerous than in the district referred to, the proportion of water deposits under natural control by the indigenous *Gambusia* must be much higher.

If the *Gambusia* is a natural enemy of the mosquito and possesses a predilection for mosquito larvae as food—and observations seem to support this theory—then it is reasonable to suppose that the fish will seek access to and by choice inhabit that class of water deposits most favored by the female mosquito for ovipositing. If this be true, it then follows that the control of mosquito production by the *Gambusia* in sections where it is indigenous, and where its distribution has been determined by natural selection, is in far greater proportion than would be indicated by data showing only the proportionate number of water deposits in which the *Gambusia* is found.

In 1919 it was the privilege of the writer to survey an incorporated town and its surrounding territory in Mississippi and located near the district where our experiments were in progress. This survey showed scores of potential mosquito breeding areas under almost complete control by the *Gambusia* which have made their way into these areas and into the town ditches and street drains in great numbers. The stocking of these areas resulted from the overflow of a nearby stream which contained large numbers of *Gambusia*. One of these potential mosquito breeding places, consisting of a small but rather deep lake, was at the outskirts of the town. The locality was being used as a dumping area for the town refuse, which had practically filled up a part of the lake.

Aside from some turbidity, due to the nature of the material being dumped into them, the waters of the lake were fairly clear but the shores were heavily overgrown with grass and weeds. Although these waters and shores seemed an ideal breeding place for mosquitoes, no larvae were ever found; thousands of top minnows were observed patrolling the shore line, investigating every nook and cranny in search of food. No one can observe the tireless activity and persistence of these little fish in their search for food, and the ferocity with which they attack and destroy mos-

No. 12. In the autumn when the creeks dry down to a series of disconnected pools the *Gambusia* are concentrated in these pools and often maintain a fair degree of mosquito control unaided. However, it is necessary to distribute the fish in proper numbers often, and to remove the masses of leaves which collect in the pools when the trees cast their leaves.

quito larvae, without being greatly impressed with their possibilities as an agent for mosquito control. Unquestionably, the town referred to, as well as many other communities in sections where the *Gambusia* is indigenous, owes much to this little fish for a very material reduction in its rate per cent of malaria through the destruction of mosquito larvae.

Briefly, the results of the two years control of mosquito production in the area referred to, were:

(1) The complete and immediate elimination of the mosquito nuisance.

(2) The reduction of clinical malaria from a rate per cent of 17.83 in 1918 to a rate per cent of 5.03 in 1920. Of the rate per cent of malaria for 1920 (5.03) a large proportion of the cases were relapses from the infections of previous years which could have been prevented only by the administration of quinine. These people gave definite histories of malarial attacks each season for two or more years. Probably not more than two-fifths of the entire number of cases occurring in the area during 1920 were due to infections received after malarial control measures were in operation.

It may be of interest to know that the rate per cent for clinical malaria was 21.6 in the non-controlled territory for the season of 1920.

The per capita cost of the control operations for the two years was,

respectively: 1919, \$2.60; 1920, \$3.08. The increase in the per capita cost in 1920 over that of the per capita cost in 1919 was due entirely to the great increase in the cost of labor.

Since the attention of the public health authorities and sanitary engineers has been directed to the possibilities of the *Gambusia* as an agent of mosquito control, many are employing them in their anti-malarial campaigns with most satisfactory results. It was gratifying to note at the last meeting of the National Malaria Committee and the conference of sanitary engineers at Louisville, Ky., that, without exception, the reports of those who had used the *Gambusia* in mosquito control during the season of 1920 were most favorable. In some of these reports it was stated that a saving of 50 per cent of the estimated cost of control was made possible by substituting fish control for the more expensive methods of the past.

The *Gambusia Affinis* is not found in many foreign countries. It is reported to be found in Trinidad, British West Indies, and in British Guiana. There is, however, no record of it having been imported to these countries, and the writer was unable to verify by personal investigations made this year the statement that it

is present. Recently it was the privilege of the writer to observe the results of mosquito control experiments where the small Cyprinodont fish, known in Barbados as the "Millions," was used. They seem to function well, though because of their small size, the individual fish evidently cannot devour as great a number of mosquito larvae as the larger *Gambusia*. Also, recently the writer had the opportunity to observe some experiments in southern Porto Rico with the top feeding fish of that section, the *Pocilia Vivipara*, where it was being employed in experiments at mosquito control.

**Application and Conclusion**

As has been remarked, the intelligent and effective use of the *Gambusia* as an agent of mosquito control requires practically no expert knowledge or training. Any intelligent person interested in controlling mosquito production can make profitable use of the *Gambusia*. As an illustration, we may take a rural home in the hill sections of one of the southern states. Usually the home is located in some commanding elevated spot with the woodlands and cultivated fields situated around it. The dwelling site is usually fairly well drained. More or less malaria occurs in the household every season. Severe cases may have occurred and possibly an infant or young child may have died with the disease. Each season there is sickness in the home—there are doctor's bills and drug bills incurred, and time is lost through sickness from the important work of the farm because of malaria, which is directly due to the breeding of *Anopheles* mosquitoes usually within one-half mile, often within one-quarter mile or less

No. 14. Results of "freshet." Cornstalks and debris from the fields deposited on the bridge and in the road by the water. The overflow of streams results in the inundation of fields from which the alluvial soil is often washed, together with much vegetable debris which would be of value to the lands.

of the home. The first step for the head of the household to take is to survey his premises for one-half mile in each direction from his home, and to note all water deposits within this radius. He should realize, if he lives in the malarious belt, that, for the safety of himself and family as regards malaria, he must consider all standing or stagnant water as a constant menace.

All water deposits within the one-half mile radius which are not absolutely essential for the needs of the farm should be filled or drained, ditches should be provided and kept clear for carrying off storm water promptly; watch should be kept for water left standing in tubs, rain-barrels and artificial containers, and this should not be permitted. A tablespoonful of water may breed mosquitoes if it stands long enough. The

water deposits which are essential for the convenience of the home, or which are too extensive to be drained or filled (ponds, springs, creeks, etc.), should be thoroughly cleared of debris and vegetation and stocked with top minnows. At least once each month, and better twice a month, during mosquito breeding season (April to November), an inspection should be made of each water deposit to make sure that the waters are free from debris and that the shore lines are cleared of vegetation. This condition is necessary if the top minnows are to function properly.

If mosquito breeding areas located on his neighbor's lands are nearby and are a menace to the health of the householder and his family, an opportunity is here afforded him to interest his neighbor in a co-operative effort at mosquito control which may spread and develop into community action.

Certainly this program presents no serious difficulties to the fairly intelligent, progressive householder in our rural sections, neither does it require the expenditure of any considerable sum of money, and it promises very profitable results in improved health and efficiency for the inmates of the home where it is put into effect.

No article on malaria should be concluded without mentioning the fact that *quinin is the only known remedy for malarial infections*, and, if taken in proper dosage for a sufficient length of time, it acts as a specific. The state boards of health of many of the southern states are prepared to give full information regarding the use of quinin for malaria, if such information is not available from a physician.

No. 13. A "freshet" on Bogue Chitto Creek. The heavy rains of the winter and early spring often cause "freshets" or overflows in the creeks. They escape from their banks and flood the surrounding lowlands. When the "freshets" occur, as they sometimes do, after the crops are planted and growing, great damage is done to the growing crops by the water.

# Mexico Celebrates First Baby Week

## Fifty-five Thousand Mexicans Appealed to Through Elaborate Child Welfare Exhibits

BY HELEN BOWYER, EXECUTIVE SECRETARY DE LA SEMANA DEL NIÑO, DEPARTMENT OF HEALTH, MEXICO CITY, MEXICO

THE Mexican Department of Public Health is one of the major activities of the Federal Government. It is organized under its own *Jefe*, or Chief, who is responsible only to the President of the Republic. When, therefore, it decided to hold a *Semana del Niño*, or Baby Week, as its contribution to the Centennial of the Nation's Independence, it found itself with both the authority and the resources to do it on an effective scale.

There had never been a Baby Week in Mexico or a big child welfare demonstration of any sort. The staff was, therefore, unhampered by precedents of any kind and immediately opened up relations with the United States, England, Canada, and New Zealand appealing to both their Governments and their private organizations for all the cooperation they could bring to bear. Never was appeal more warmly answered and perhaps no Baby Welfare Exhibit ever held represented the personal good wishes of so many social workers in so many different parts of the world. Even from troubled Russia came inspiration in the shape of those wonderful posters which the English Friends had prepared for the Moscow Maternity Exposition.

There are in Mexico no such large halls as are available in American cities and so it was necessary to stage the Exhibit in the ground floor rooms and the *patios*, or inner courts, of the *Departamento* Building. As the week of its celebration, September 11-20, came towards the end of the rainy season when heavy showers might be expected daily, the *patios* were roofed over with a roofing of gray and white striped canvas which harmonized with the soft grays and tans of the booths. The rough stone floors and square stone pillars among which these booths were set, the great palms and flowers that walled the aisles between them, and the long vista through the *patios* from the *Paseo de la Reforma* to the *Calle de Madrid*, gave an effect both beautiful and picturesque.

The posters with which the booths were hung were almost all painted for the occasion or made over by Mexi-

can artists from material sent by other countries. Most of them were in soft, rich colors which drew the attention of the beauty loving Mexicans as black and white would not have done.

### Many Baby Welfare Booths

Each booth represented a major division in the field of Baby Welfare. Among those that attracted the most interest were the exhibits on eugenics, on prenatal care, those on the care and feeding of the baby, infant mortality, baby diseases, poverty and defective housing in relation to the child, public nurses and welfare stations, the country child and the defects and limitations of his environment, and the things that other countries are doing for their babies. There was also a special exhibit for fathers and one for mothers. The latter, which was prepared in part by Elena Torres of the *Consejo Feminista*, or Feminist Organization, was unique in that it emphasized those responsibilities of women which theoretically lie outside the home but which in reality condition it. Wages, unemployment, housing, public sanitation, cost of living,—all these and other problems were called to the attention of the women of Mexico, who, like the women of other lands, will have to take a hand in solving them if they are to be solved at all.

Other interesting exhibits included one prepared by Señorita Emmy Ibanez of the *Sociedad Protectora*, a new orphanage for boys, and one by Señor Roberto Modellin on the nutrition work of the *Dirección General de Educación* which daily provides breakfast to hundreds of school children whom poverty would otherwise compel to go without. A charming exhibit of baby clothes designed by Miss Mary Pearson on the simplest and most inexpensive lines awakened so much interest that three afternoons Miss Pearson and a group of assistants were kept strenuously busy cutting and giving out patterns of the garments.

The exhibits were supplemented by such practical demonstrations as are usually found in a standard child

welfare exposition in the United States. There were demonstrations in the modifying and preparation of the baby's milk for the day, and in the feeding, bathing, and clothing of the baby. In the booth on the care of the eyes a specialist gave appropriate object lessons, while a group of students in charge of the booth on the care of the teeth directed in tooth brush drills a group of children picturesquely costumed for their parts. As interesting a demonstration as any were the milk tests conducted daily by a group of chemists belonging to the Department,—tests for bacteria, for acid, for proteid contents, etc. The tests were accompanied by popular talks on the essentials of a proper milk supply for a city like Mexico.

The Department is very much alive to the importance of birth registration and made a drive for it one of the features of the *Semana del Niño*. A booth was hung with posters setting forth the advantages of the *Registro Civil* and all the possible penalties of its neglect. As a special inducement, all children registered during the week were promised a certificate signed by the President of the Republic. Near the registration booth a room was fitted up for vaccination and thither babies who had had their names inscribed in the *Registro Civil* were shepherded for the further duty of immunizing them against smallpox. It had been intended to run these two activities only in the mornings, but the demand was so overwhelming that both had to be kept open all day.

The *Paseo de la Reforma* is a broad and beautiful boulevard which, as it passes the Department, is divided into three roads by wide strips of sward. The road in front of the Department wall furnished the only available site for the demonstration playground which the staff of the *Semana del Niño* was so anxious to operate, and for the "Little Theater" which was to house the *Conferencias*, the *Comedias*, the Kindergarten *fiesta* and other program features. Two large tents were therefore pitched out on the roadway, the one fitted up with a stage, the other with a sandbox, teeter, swing, and two sliding boards.

Playgrounds, in the American sense of the word, are almost unknown south of the Rio Grande, and young Mexico went wild over this one, sprung up so mysteriously over night. The children literally stood by the hundreds waiting their turn at swing and sliding board, going down the latter in an uninterrupted stream. There was never a day when there could have been less than three thousand youngsters in attendance, and several days there must have been more.

### Kindergarten Fiestas Popular

The kindergarten *fiestas* were among the most charming features of the week. Under the untiring leadership of their *directora*, the Kindergarteners of the *Direccion General* gave four programs in which, by means of games and songs, their tiny charges dramatized such fundamentals of health and right living as good food, the liberal use of milk, efficient housekeeping, personal cleanliness, sunlight, and fresh air. The *Comedias* were fairy Health Plays, two of them written especially for the *Semana del Niño*, and two of them translated from the plays of the National Tuberculosis Association and the Rockford (Ill.) Public Schools. They were given by the pupils of leading schools in the city and were received with such enthusiasm that the Department is issuing a book of such plays to continue the propaganda.

The *Conferencias* were short lectures given by eminent physicians of the city under the leadership of Dr. Alfonso Pruneda, General Secretary of the Department. They were given twice a day, on such subjects as heredity, prenatal care, the feeding and care of the baby, and most of the other aspects of child care that would be covered in a standard American exhibit. In addition to this, a group of students from the National School of Dentistry gave brief popular talks on the newer aspects of dental science, such as the part which the proper diet of the mother during the prenatal period and the breast feeding of the child during the first nine months of life bear in the formation of a strong set of teeth.

The program of the *Semana del Niño*, however, was not confined to the local of the *Departamento de Salubridad*. Each day of the week had some special feature which was celebrated in some other portion of the city. Sunday was the *dia de la bandera*, whereon pennants of royal blue, bright with the insignia of the Department, were hung from the win-

dows of the homes of all the babies who had chosen the last few days for their *debut* on earth. On Monday little *fiestas* were given in all of the primary schools. Short talks on personal hygiene and on the care of the teeth were sandwiched in between the more festive features and every child was presented with a tooth brush and a copy of the Metropolitan Mother Goose done into Spanish verse by the Mexican poet, Solon de Mel.

On Tuesday came the *Procesion Infantil* in which the vanguard of Mexico's babies joined their insurgent brethren in the United States in voicing their rights to intelligent parents, decent homes, clean milk, pure water, and all the other "minimum essentials" which the modern infant has been taught to demand. Over a hundred automobiles, hung with posters and banners, bore the young agitators through the principal streets of the city, their oncoming well announced by military bands. The way, indeed, had been prepared for them by sympathizers in the War Department who from their airplanes had bombarded the city with the *manifestos* of the youthful insurgents prepared with the connivance of the *Departamento*.

On Thursday and Friday the good will of the *Semana del Niño* was extended to the mothers and babies in the maternity wards of the hospitals and in the children's institutions. A program of music and little talks was followed by refreshments and the children were presented with toys, tooth brushes, and the Mother Goose Rhymes. Each mother of a new born child, moreover, was given a complete layette provided by a group of women who are accustomed to so remember their poor neighbors on occasions such as this.

### Fathers' Day Celebrated

Saturday was the *dia de los padres*, dedicated, as its name indicates, to propaganda among the men of the city. *Conferencias* were delivered in the leading clubs and industrial establishments and the very popular "message to fathers," first used at the Pittsburgh Baby Week, was distributed.

The *Departamento*, indeed, made the *Semana del Niño* the occasion for the distribution of a large amount of literature on the subject of child welfare. Its translation of the Children's Bureau publication, "Prenatal Care," was exhausted before the week was over. The Metropolitan Life Insurance pamphlet, "The Child," ran it a very close second in instant popularity. A booklet on the "Care of the

Eyes" by Dr. Joquin Izquierdo, a leaflet on the "Care of the Teeth" by Dr. Cordova, Director of the National Dental School, a "Message to Mothers" by Elena Torres of the *Consejo Feminista*, and a "Mother's Calendar," by the Executive Secretary, were Mexico's own contributions to her Baby Week.

There could be no question of the success of the Exposition. In spite of other and more spectacular attractions of the Grand Centennial, the Department found itself almost swamped by the crowds that poured in to the *Semana del Niño*. On the last day of the Exhibit the attendance exceeded twelve thousand.

The Department hopes that its Baby Week will work out in some of those permanent benefits to childhood that have followed similar expositions in the United States and England. It is already organizing a Division of Child Hygiene and hopes, in connection with the *Direccion General* and Government of the Federal District, to inaugurate some other child welfare activities.

### Movies Aid in Eye Saving

"Saving the Eyes of Youth" is the title of a new moving picture film produced for the National Committee for the Prevention of Blindness.

Although the terrible disease that has deprived ten thousand babies in our own United States of their sight may come to any baby, black or white, rich or poor, its results are most keenly felt where the struggle for life is greatest, where the sun never shines, where overcrowding robs the very air of its health-giving qualities, where ignorance and misery abound. The picture portrays a baby born in such surroundings; it shows the lowly tenement, the mother and her new-born child, the discovery of something wrong with the baby's eyes, the gathering of the neighbors with their well-meant but worse than useless advice, the little sister who has been an attentive listener to health talks at school, the arrival of the district nurse, the hurried trip to the hospital, the sorrowing mother waiting in the hospital corridors for the word that shall mean all to her loved child, and the kindly doctors and nurses who return the child with eyes that see to his rejoicing mother.

If the experience of this mother and her child as told by the film shall save the sight of even a few of these who might otherwise spend their lives in darkness, its work will be well done.

## Value of Pedographic Records

**P**ALMISTRY,—the empirical art of interpreting by the lines of the hand the personality, trend, and particular dangers of failure in a given subject—claims many devotees. From prehistoric times until the present day sufficient numbers of people have lent faith to readings of the lines of the hand to support armies of chiromantists and to develop in palmistry a very definite system of divination. The fact that the strength and direction of connecting fibers are purely mechanical anatomical devices and that the development of mounds which are taken to indicate logic, energy, materialism, or prudence depends upon the uses to which the hand has been put and may be increased at will by exercise does not lessen the popular interest in their predictive meaning.

Attention to the lines of the hand could with great profit be transformed into universal interest in the lines and contour of the feet, for there the lines do tell a true story of habitual postures, of poise, of reserve energies, or of neglect, of vanity, abuse, and fatigue. How many people at an evening party would be cheerful or willing candidates for character reading from the soles of their feet? How many people would be able to regard with equanimity a pedographic record from youth on through to maturity? What percentage of perfect feet would any typical community disclose?

Serial pedographic records are often advisable. They may be considered necessary in the handling of abnormal foot conditions, as a check on progress. Mere inspection may enable a satisfactory diagnosis of weak foot, but it affords no precise means of measuring whether progress toward correction is satisfactory.

In the pedographic records of Dr. Jacob Grossman five prominent signs are taken into consideration of abnormal foot conditions of children: (1) the pedograph picture; (2) the contour line of the foot; (3) the height of the scaphoid bone; (4) the muscular development of the soles of the feet, especially those under the arch of the foot; (5) the presence or absence of the juvenile fat pad.

In taking the imprint the individual is seated, the leg extended, and the bare foot painted with an iron solution. The foot is then hastily placed on blotting paper and the individual is told to place all the weight on that foot. At this point the contour line

is drawn by using a pencil or pen held at right angles to the plane surface. This contour line demonstrates the amount of inversion of the ankle, or eversion of the heels and heel cords. A solution of tannic acid applied to the foot imprint turns it a jet black, giving a record which can be preserved indefinitely.

In an effort to standardize the findings in children Dr. Grossman made an intensive study of one hundred

children, selected because they have no symptoms referable to foot disturbances, and arrived at averages from which degrees of abnormality can be reckoned. The analysis of the conditions found in this one hundred children disclosed the fact that more than one-half of what were assumed to be normal feet were abnormal. In these cases particularly the value of pedographs of all children was emphasized so that pathological foot conditions can be detected early and prophylactic measures instituted where necessary.

## Movie Health Car for Negroes

**T**UBERCULOSIS prevention and sanitation are literally being brought home to the rural colored population of North Carolina by means of the Motion Picture Health Car of the North Carolina Tuberculosis Association. Dr. E. T. Ransom exhibits the pictures, and lectures explaining them.

The Health Car was purchased from the sale of tuberculosis Christmas seals among the colored people of the state. It is in the field constantly, its itinerary covering the whole state, one week being spent in each county where from six to ten shows are given.

The visual education part of Dr. Ransom's program includes a one-reel film entitled "Mrs. Brown versus the High Cost of Living." This explains the happiness and comfort which come from a clean kitchen and attractive service in the home, teaches the housewife how to economize, and

the proper food for children. "Celes and the Ambulance Corps," a film from the Community Service Bureau, and "Jinks," a comedy on tuberculosis, are other instructive films of entertaining vein. Six or seven reels dealing largely with health and sanitation, all told in story form, are shown at each entertainment. These include two films on tuberculosis, one on public health nursing, one on oral hygiene, and various ones on phases of agriculture which are lent by the United States Department of Agriculture.

In connection with the motion pictures, Dr. Ransom lectures to his people on home and community sanitation and the prevention of disease, especially that of tuberculosis. Since many cases of tuberculosis are found in the communities he visits, this disease is discussed at some length.

The Health Car is popular in the communities which it visits and the

North Carolina's motion picture Health car which under the direction of Dr. E. T. Ransom is carrying to the rural colored districts of the state the message of tuberculosis prevention and care.

afternoon and evening shows are crowded with old and young, curious to see the pictures and eager to better their condition. During a six months' period Dr. Ransom gave 148 exhibitions in twenty-five counties, witnessed by 34,148 persons. At each performance he gave a health lecture besides visiting 831 persons in their homes. The car during that period traveled 3,887 miles.

"The colored people at large feel very grateful to the North Carolina Tuberculosis Association for what it is doing to promote health in the rural sections of the state," says Dr. Ransom. The close of each performance brings expressions of gratitude from the audience and regret that, on account of ignorance of such facts, lives have been lost. Everywhere the exhibit promotes permanent health work.

## Cooperative Attack on Disease

THE science of chemistry has undergone a complete revolution in the last twenty years and the newer developments call for cooperative effort on the part of scientists of the highest type—chemists, physicists, biologists, pathologists, bacteriologists, and pharmacologists—in intensive chemical research on the problems of health and disease. A committee appointed by the American Chemical Society, as the result of three years of intensive study, has just issued a report under the title: "The Future Independence of Progress of American Medicine in the Age of Chemistry," which "it is the hope of the Committee will be carefully read and discussed by physicians and surgeons, by mothers and fathers, by educators, by hospital directors and trustees, and all others whose hearts are interested in the welfare of future generations of American children."

The problem of fighting disease is fundamentally a chemical problem, says the report, and one which demands the cooperative effort of the chemist, the physicist and those experts in the fields of biology who are most immediately concerned with the scientific study of disease, namely, the pathologist, who studies the changes in the organisms produced by disease; the bacteriologist, student of our chief enemies, the micro-organisms or disease germs, and the pharmacologist, who investigates the effects of drugs of all kinds on the organism.

The biologist—pathologist, bacteriologist, or pharmacologist—would be wholly at a loss in a thoroughgoing effort to chart the seas of disease and health without the aid of the chemist and physicist to study minutely and exhaustively those chemical and physical questions which form the very breath of life.

We have in this country a number of excellent research institutes devoted to medical investigations, with staffs of the highest caliber. It must be said, however, without fear of con-

tradiction, that there is not a single organization whose purpose is a determined co-operative attack on the problems of disease and health, where intense chemical and physical research goes hand in hand with the medical and biological study of disease.

The importance of chemistry and physics has been recognized, but the direction of research is still essentially in the hands of medical men. No one of the scientific groups alone should be entrusted with the leadership. All are needed for coping successfully with the complex and formidable problems.

### Chemistry and Medicine

Each human body is now recognized to be a chemical factory in which the most complicated chemical and physical changes are continually taking place, hence there has been a return to the earlier views as to the relation of chemistry to medicine.

Antitoxins, the most powerful weapons in combating invading disease germs, are chemical substances of specific curative power, but of unknown composition and never isolated as yet as pure principles. Co-operation of the medical investigator with the chemist (Dr. John Howland of Johns Hopkins and his collaborators) has led to the recognition of the fact that in rickets, the scourge of many thousands of children, there is a deficiency of such common chemical components as lime and phosphate in the blood—"a discovery that by the same co-operation must ultimately lead to successful preventive methods. But how long must the thousands of little victims wait for relief?"

"If such work is to be successfully prosecuted in our midst," says the report, "it must be through the practical idealism of America, which, can here find abundant outlet in proving such conditions as will direct the future energies of chemistry in America to this greatest blessing to mankind, a blessing which will not be confined to its own borders, but will stretch out its helping hands to all suffering humanity."

The investigators find that constructive chemistry can and must render to medicine in the prevention and cure of disease services which must be used along these three lines of attack:

(1) The preparation of the specific medicament for the cure or alleviation of the specific disease.

(2) The isolation, study, and, if

needed be, the artificial preparation of pure organic principles of fundamental importance to our life, such as principles of secretion of our body organs, of which a deficiency or excess would cause disease (goitre, acromegaly, dwarfism, gigantism, and probably diabetes, gout, etc.).

(3) The complete ultimate analysis of the constituents of our body cells, of the components of the blood, of tissues, together with the complete ultimate analysis of the components of our foods—so that we may have complete knowledge of the body in health and of what it needs to preserve its health.

Chemistry may help cure pneumonia, for "there is every reason to believe," says the report, "that a modification of quinin can ultimately be prepared that will be a specific cure of pneumonia."

Three scourges lack specifics, the report says. "There is a tremendous, practically undeveloped, field for great work here," says the report; "specifics are now needed for tuberculosis and pneumonia, and perhaps even for cancer, to which a large proportion of mankind falls a victim."

Formerly we got most of our synthetic medicines from Germany. The facilities for chemical research in that country are contrasted with those in this country, much to our detriment. The research resources of England, France and Japan are also recounted.

The Chemical Foundation, of 81 Fulton Street, New York City, of which Francis P. Gowan is president, has undertaken to distribute upward of one million copies of the report.

This Committee worked under the chairmanship of Dr. Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association of the United States and past president of the American Chemical Society. Its membership includes Dr. John J. Abel, Professor of Pharmacology, Johns Hopkins Medical School, Baltimore; Dr. Carl L. Alberg, director, Food Research Institute, Stanford University, Cal.; Dr. Raymond F. Bacon, director, Mellon Institute for Industrial Research, Pittsburgh; Dr. F. R. Eldred, Chemical Consultant, Eli Lilly & Co., Indianapolis; Dr. Reid Hunt, Professor of Pharmacology, Harvard Medical School, Boston; Dr. Treat B. Johnson, Professor of Organic Chemistry, Yale University, New Haven; Dr. Julius Steiglitz, Chairman of the Department of Chemistry and Past President of the American Chemical Society, and F. O. Taylor, Chief Chemist of Parke, Davis & Co., Detroit. The report was drafted by Dr. Steiglitz, Dr. Hunt, Dr. Johnson, Dr. Eldred and Dr. Herty, and was unanimously approved by the entire Committee.

## The Problem of Special Education for the Deaf Child

THE opening decades of the Twentieth Century have witnessed great advances in every department of public health, but none greater than the improvements which have been made in the education of the deaf child. The very recognition of the fact that uneducated deaf people are a menace to themselves and others was a greater forward step, but when Helen Keller was led from blank silence into a world-famed literary career, the possibilities of salvaging the deaf became widespread.

One of the greatest obstacles has been the prejudice against beginning treatment early, the mother, aided and abetted by the soft hearted physician, optimistically hoping that hearing will develop and delaying training until the years of language formation have been passed. During this period the mind of the deaf child is struggling to establish mental contact with its mother who in her ignorance can reply to the child's interrogative gesture only by a smile, a nod, or a shake of the hand. After the age of seven it becomes increasingly difficult to train these children. Their training should begin at three, a training in which the expert teacher, the mother, and the physician must cooperate.

The medical profession has been singularly backward in recognizing the fact that for the most part the solution of this problem lies in the development of the child's mind through educa-

tion rather than by attempting to improve the child's hearing. Certainly, no promising method of restoring hearing, even in part, should be neglected but it should never be held as a reason for delaying training which to be really successful should be initiated at the earliest dawn of intelligence.

## Social and Economical Aspects of Insurance

INSURANCE is fundamentally social in nature. Whether purchased to stabilize a business, to protect against fire losses, to save dependents from poverty, or to provide against physical incapacity in the proposer himself, it seeks to apply to the unpredictable circumstances of the individual life the precise percentages which are easily calculable for the group, making possible the distribution of the risks of any reasonable contingency.

The socially minded incline to insurance. It is the man capable of holding himself to a remote objective who through insurance accumulates a fund to provide against the crises possible in his business, who employs an endowment plan for the education of his children, or who capitalizes his own earning power. The very stability that the sense of protection affords is socializing in effect and tends to maintain the social position of the protected group.

The least advanced citizens are the least protected. It is noteworthy that a broadened scope of protection has usually been accompanied by better health practice and the control of conditions which make for the improvement of the health conditions of the group affected. The excessive mortality rate of the class of people covered by small policies has been the subject of special investigation which discloses the fact that the group which carries the smallest insurance against the unforeseen contingencies of life are the most prone to neglect sanitation, to ignore nutritional requirements, or to observe the simplest laws of hygiene. In this economic reasons are to be considered, but inevitably as man visualizes his future and sees himself as a social factor, he conserves his forces and directs his activities to contribute toward the remote social objective.

In point of fact, social position to a large measure determines the insurability of a life. The selection of lives from the viewpoint of insurance is not entirely a matter for the medical profession. Lister<sup>1</sup> in his recent book on "Medical Examination for Life Insurance" expresses this in his statement that "a man with an insurable form of heart disease is acceptable only if his

<sup>1</sup>Edwin Arnold & Co., London, 1921.

occupation is regular and sedentary and his exercise discreetly governed. A tuberculosis danger is regarded less anxiously in a farmer than in a draper or clerk." It is because final assessment is on the basis of the social and hereditary background that the clinical experience of the physician must be modified by the analysis of the actuarial department. The significance of early breakdown may be directly due to position in life. Lister gives 1908 figures on mortality by occupation, ages twenty-five to sixty-five, varying from 524 for clergymen to 1,808 for inn keepers. Brewers are second only to inn keepers in their high mortality while musicians, surprisingly, rank third, whether from temperament or habit Lister does not venture to state.

Of interest in the evaluation of lives is what some actuaries consider to be an "attenuated vitality" in people living out of their native habitat. The peregrinations of men have long been considered highly important public health factors, but they are only now beginning to be considered in their larger aspects. The social uses of insurance, therefore, must be held to include the collection and analysis of all relevant data and their scientific application to the affairs of men, in the field of health no less than in the realm of economics.

---

### Food Infections and the Spread of Food Contaminations

IN JORDAN'S admirable book on "Food Poisoning"<sup>1</sup> is a table of outbreaks of disease due to food, occurring between October, 1913, and October, 1915, based on data gathered from a press clipping bureau and other sources. The figures as given include 657 group and family outbreaks involving more than five thousand persons, and the author estimates that "probably several thousand outbreaks of food poisoning in families and larger groups, affecting at least fifteen thousand to twenty thousand persons, occur in the United States in the course of a year." This estimate of course includes all types of food poisoning due to infection, decomposition, and the presence of poisonous chemicals of various sorts.

During the past few years the influence upon health of foods contaminated with various types of bacteria has been studied with particular care. Outbreaks of botulism have been numerous and have attracted wide attention,<sup>2</sup> but true food infections due to members of the Gaertner group of

bacilli have been surprisingly hard to find. This type of disease is relatively common in England and still more frequent in Germany, but public health workers have come to feel that in the United States clearly demonstrated infections of this kind must be exceedingly rare. Professor M. J. Rosenau of the Harvard Medical School has been engaged in a comprehensive study of the subject for the National Canners' Association for a period of four and one-half years without finding a single authentic case until the present time.

At last patience has been rewarded and Rosenau and Weiss report a quite typical outbreak among a group of students in Washington, D. C., in which eighteen out of twenty-five students who had attended a spread at a fraternity house were affected. The epidemiological evidence pointed clearly to bread pudding and *B. enteritidis* of low virulence was isolated from the food in question. The method by which the bread pudding became contaminated was uncertain although milk is naturally suspected and, as is common in such outbreaks, the pudding had been made early in the morning and stood all day in a warm kitchen, giving ample opportunity for bacterial growth.

By a curious coincidence it happens that a similar case has also just been reported by Krumwiede.<sup>4</sup> The infecting organism in this instance was *B. suispestifer* (distinguished from *B. enteritidis* by failure to ferment arabinose and to blacken lead acetate media); and the food was tapioca pudding. The particularly interesting thing about this second outbreak is the fact that the raw materials used for the pudding had been thoroughly heated and that contamination was apparently transferred from another food, which was subsequently itself heated and consumed without harm. It is evident that we must still be on our guard against food infections of this type and that the ways by which contamination may be spread are many and devious.

---

### Therapy Based on the Control of Intestinal Putrefaction

APOSTLES of long life, from Cornaro to Stephen Smith, have always placed stress on moderation in the use of the high protein foods, and most of them have laid emphasis upon the value of that most primitive of human diets, milk. Since the time of Bouchard (1884) evidence has accumulated to show that the putrefactive decomposition of protein foods in the intestine leads to the formation of products which are toxic and which when absorbed produce very definite transient conditions of malaise; while it has been suggested that such autointoxications

 2. Rosenau, M. J.: Preventive Medicine and Hygiene, Appleton, New York, 1921, p. 706.  
 3. Rosenau, M. J., and Weiss, H.: Jour. A. M. A., 1921, vol. 77, p. 1948.  
 4. Krumwiede, C., Provost, D. J., and Cooper, G. M.: Paper read before the Society of American Bacteriologists, Philadelphia, December 28, 1921.

may be of profound importance in connection with the acceleration of degenerative diseases of various types.

As early as 1886 Hirschler, Miller, Ortweiler, and others suggested the feeding of carbohydrates as a means of counteracting such putrefactive protein decomposition. The work of Tissier, and above all of Metchnikoff, attracted wide attention to the possibility of attaining the same end by modifications in the bacterial flora of the intestine. Metchnikoff's advocacy of the use of milk soured by *B. bulgaricus* or by ingestion of cultures of the organism itself, as a method of promoting longevity attracted wide attention fifteen years ago, but results were conflicting and the practice of sour milk therapy gradually fell into disrepute.

The questions at issue have at last received at the hands of Rettger and his pupils a thorough scientific analysis which apparently explains conflicting earlier results and places the control of intestinal putrefaction upon a substantial basis; a result which constitutes one of the most important contributions to bacteriology accomplished within the past decade. The principal points brought out by these investigators<sup>1</sup> may be summarized as follows:

*B. bulgaricus* is an organism which is very active in the *in vitro* souring of milk but its implantation in the intestine is exceedingly difficult. The closely related *B. acidophilus* on the other hand is normally present in the intestine in small numbers, is easily stimulated so that it takes a predominant place in the intestinal flora, and may easily be implanted by the feeding of pure cultures. It may be increased so as to dominate the intestinal flora either by administration in the form of a pure culture or by the feeding of lactose or dextrin, or by a combination of these two procedures; and the value of feeding either sweet or sour milk under ordinary conditions lies, neither in the bacterial flora of the milk nor in the effect of the acids which it contains, but in the stimulating effect of the lactose upon *B. acidophilus* already present in the intestine. When Metchnikoff and his associates fed milk containing *B. bulgaricus* and thought that they detected a corresponding increase of *B. bulgaricus* in the stools they were really observing an increase in *B. acidophilus* due to the lactose fed and were misled by the similarity of these two related forms. The evidence presented by Rettger as to the possibility of affecting a change in the bacterial flora within a period of four to six days by feeding *B. acidophilus* or by feeding lactose or dextrin is complete and convincing and already<sup>2</sup> reports

are coming in as to favorable clinical results obtained by such methods of treatment in a wide variety of pathological conditions. As a result of these investigations it seems probable that therapy based on the control of the flora of the intestine will once more come to the front and that its possibilities will receive exhaustive study during the next few years.

### Male Dress Reform—The Necessity for Bodily Ventilation

IF INDUSTRIAL hygiene has brought forth one incontrovertible fact, it is that there is a direct relationship between the ventilation of the work room and the efficiency of the worker. Physiologists have determined that the reason that moist warm temperatures reduce efficiency is because of the difficulty of getting rid of bodily heat, particularly in those situations in which the atmosphere is stagnant. Conversely, those who live and work in an environment approaching that of the outside air are not only more useful workers but they also lead longer, healthier lives.

The reason is not far to seek. Man gets rid of his excess heat by perspiring and this physiological process is as necessary to his well being as is panting to that of a dog. Unless this perspiration is evaporated and heat loss produced thereby, he is surrounded by an envelope of moist air, an excellent nonconductor of heat, and in consequence, a greater or lesser degree of heat prostration results. Thus many of the ill defined ailments observed in certain trades are nothing in the world but chronic heat poisoning. These facts are well recognized and factory laws in general require that workshops shall be well ventilated.

It is curious that this principle has not been more generally applied to the clothing of man, *i. e.*, that steps have not been taken looking to the improvement of the body of the individual.

Man possesses enormous powers of resisting cold, yet there seems to be a deep-rooted antagonism to working and living in a temperature much below 68° F. We are taught from childhood to be afraid of taking "cold" but it would be far more logical to teach the danger of taking "heat." The modern house is so constructed that it almost duplicates the climatic conditions of the shady Tropics and out-of-door games and other artificial exercises are necessary to keep healthy a body which normally should be maintained by the struggle to obtain food.

The clothing which is worn by the average male, in the Temperate Zone, contributes not a little to the bad ventilation of the body and by reason of its many constrictions, it reduces the exercise of the musculature very considerably.

1. Rettger, L. F., and Cheplin, H. A.: A Treatise on the Transformation of the Intestinal Flora with Special Reference to the Implantation of *Bacillus Acidophilus*, Yale University Press, 1921.

2. Cheplin, H. A., and Wiseman, J. R.: Boston Med. and Surg. Jour., 1921, vol. 135, p. 627.

The feet are incased in stockings which hold both heat and moisture and over this layer are shoes made of leather and canvas and rendered almost water-tight by an outer coating of wax or enamel. They bind the foot to deformity and its muscles are atrophied by non-use. The leg is constricted by stocking and garter, outside which is a pair of trousers which bind the knees, thighs, and hips. The thighs are incased in drawers which may extend to the ankles binding calves and knees still more and tightly buttoned over the hips and around the waist. In the case of breeches, motion is still further restricted by their being buttoned from the knee downwards and this is accentuated by puttees, either of stiff unyielding leather or a bandage of wool tightly applied. Trousers or breeches tightly encircle the waist and to make sure that the abdominal muscles shall be thoroughly crippled, a belt of leather or non-elastic cloth is worn. An undershirt of cotton or wool envelops the body from the neck almost to the knees and perhaps from the shoulders to the wrists. It may interfere with respiration and over it is a shirt, with constricting bands of stiffly starched cloth which bind the neck and wrist. In the case of the dress shirt, a cuirass-like plate extends from the supra-strenal notch to the symphysis pubis. A stiffly starched collar which impedes the use of the muscles of the neck, and a necktie of no imaginable use whatsoever, top off the shirt. A snug vest of cotton or wool tightly clinches the thorax, only to be covered by a coat which restricts the shoulders, arms, and trunk. Add to this a heavy overcoat or raincoat and a hat which tightly encircles the cranium and the costume is complete, unless a cane, which is necessary in order that this poor be-swaddled male may walk, be included.

Women have displayed far more intelligence in reforming their clothing along hygienic lines. A man's clothes average about nine pounds in weight, a woman's usually less than five and it is a well known fact that a girl in an evening gown can dance a man in a dress suit to death.

The solution of the problem lies, of course, in the reform of men's clothing. The innumerable failures to reform women's dress by direct methods and the accomplishments of fashion to that end point out a general line of attempting this. The improvements which have been brought about in female garb were not too difficult to produce because the fashion of women's dress is in a constant state of mutation and if a woman can be shown that a certain thing is stylish, she will eagerly adopt it. Not so with man. He fatuously cleaves to the necktie, a vestigial remnant of the Middle Ages; he demands a ribbon for his hat for no other reason than that the floppy head gear of

Louis XIV was liable to be blown off; buttons which once supported a sword belt still adorn the back of the cutaway of the Disarmament Era and three or four buttons at the cuff are the fossilized relics of the days when men used to roll up their sleeves. Men cling conservatively to uncomfortable, unhygienic garments and they will stiff-neckedly resist a change unless there is a subtle appeal to their vanity.

Changes are coming slowly; underwear is being improved; the soft-collar and the sports shirt are steps in the right direction; the War popularized a shoe which somewhat approaches the shape of the foot, but, unfortunately, there remain to be worn out a lot of puttees. It still is impolite for a man to appear in his shirt-sleeves; walking without a hat is frowned upon, and the man who attempted to traverse Fifth Avenue in really hygienic clothing would continue his journey in a patrol wagon. Yes, the ideal is still a long way off. A pair of sandals and a loin-cloth would be about right, but, as Carlyle has pointed out, such a garb would detract from the dignity of the Courts, so it must be said that the one-piece dungaree which automobile mechanics wear is about the best to which we have attained at this stage of our sartorial development.

---

### The Danger of Using the Mouth as a Pocket

THE study of Chevalier Jackson's epoch-making work in bronchoscopy and esophagoscopy cannot but impress the reader with the danger of using the mouth as a pocket. The list of foreign bodies removed by these methods is a legion and includes such familiar objects as coins, thumb tacks, hair pins, safety pins, shingle nails, staples, and collar buttons. As might be expected, children contributed such articles as toy jacks and grains of maize, but it is surprising that such a large number of the patients are adults. Children carry various objects in their mouths because they have not yet learned that the sole function of the mouth, aside from speech and sound production of other sorts, is that of a portal of entry for food and drink, but evidently many adults never learn this lesson. In many trades, workmen habitually use the mouth as a storage place for such things as nails, cotter-pins and the like, a dangerous and reprehensible practice.

The removal of these foreign bodies is a delicate operation, one not without danger. Special training and the continual practice of a highly specialized technic requiring the use of the x-ray and complicated instruments, which are really enormous prolongations of the fingers, are necessary for the extraction of things which need

never have entered the body had the simple precaution of keeping things out of the mouth been followed.

Industrial surgeons and other health workers are interested in making such operations unne-

### Is Your Mouth a Pocket?

*The mouth is the hole through which you talk and by which food and drink enters the body.*

*Put nothing else into it.*

*If you use it as a pocket for nails, pins, buttons or any other object you run a risk. Such objects may be swallowed or breathed into the tubes which lead to the lungs. The removal of such things from the body is dangerous, painful and expensive. If allowed to remain they may cause death.*

*Your mouth is not a pocket. Do not use it as such.*

essary. Since this is entirely a matter of personal hygiene, the means of prevention is the education of the individual. Warnings something like the above are therefore suggested.

## The Psychology of the Frank

SINCE March 4, 1921, the most popular indoor sport in the United States has been the evolution of schemes whereby the Government may save money. A citizenship which had just finished the inquisition of the income tax had been roused to the consciousness that somehow, somehow, the administration of our commonwealth of interest was costing altogether too much. Astute congressmen with auditory apparatus more keenly adjusted than the most sensitive dictaphone, heard the first faint whisperings of the self-communings of the people and there followed such a pruning of the plum tree as was never seen before. Reform, re-trench, re-fuse, these are the watchwords of the hour and the rain of economy fell alike on the graft and the ungraft and probably to pretty good purpose.

In the epidemic of parsimony which followed, the writer steadfastly refused to be infected; there was such a surfeit of nickle-squeezing patriotism that it seemed almost wanton that other massive brains should be applied to the task. Yet day by day the flood of Government publications which reached his desk began to make an impression until he was well inoculated with the money-saving virus, the various Govern-

ment circulars acting as the vehicle of infection.

When one receives the same monograph a dozen times over, addressed variously to "Dr. John Smith," "Smith, Dr. John," "Capt. John Smith, M.R.C., U.S.A.," "Maj. John Smith, U.S.A.," "Dr. John Smith, Attending Surgeon, St. Benedick's Orphanage," one begins to think. When one gets printed documents on every conceivable subject from "Memorial Address on the Late Hon. Hido-pholus Squithers, M.C." by your Representative, to "The Prevention of Flat-Feet in Sows" by the Department of Agriculture, the suspicion is apt to be created that all is not sanitary in Denmark, especially when these documents come in bushels, flocks, and parasangs. Also there are the form-letters, a little more individual in their touch, but nevertheless obtrusive invasions of personal privacy. One government burcau wants to know if my daughter is fond of sweets, bites her nails and talks in her sleep; another asks me to collect data on the importation of snails, while another asks me what I have been doing about eugenic legislation. Having collected these informative facts they are compiled, published, and distributed and the vicious circle continued.

Once one realizes that he has succumbed to the infection, he starts hunting for a remedy, frequently without waiting to trace the fault to base and in this instance the antidote which first suggests itself is to control the printing and multi-graphing which is done by the Departments. Some fairly definite measures are now in force to control printing but the mimeograph and neostyle are helping to dodge them and even if these duplicating devices were controlled, carbon paper and typewriters would continue the flood. The basic fault lies not in what is printed or how it is manifolded but in how it is distributed.

"Then the remedy lies in the mailing lists, let's revise 'em," cries Economy. "Very true, but how will you keep them automatically revised?" answered Practicality.

The fault lies in the use of the frank. It is so easy to slip something into an envelope bearing the penalty mark and to drop it into the mail chute. Why worry if Dr. John Smith gets a dozen copies of a circular on a subject about which he knows little and cares less, "It doesn't cost anything!" Doesn't it though? It costs the envelope, the paper, the printing, the clerical services and the mail charges. Of course the total of these for a single piece of mail is infinitesimal but when multiplied by millions it runs into pretty big money—money of which there is no accounting. That is the great evil. Nobody can say accurately how much is the annual postage bill of the Legislative, Judicial, and Executive branches of our Government, although it is estimated at about

\$14,000,000. It is impossible to determine whether or not the Post Office Department is being operated at a real loss so long as the franked envelope is in use. There is no limit to the amount of mail matter which any agency of the government may send out except the quantity of stationery and printed matter which a Department may secure and induce the Government Printing Office to mail. As for the abuse of the frank, it has been estimated that at least 2 per cent of letters franked are not properly official business.

The remedy is simple. Abolish the frank and substitute therefore government stamps which must be bought from the Post Office Department at current rates with funds which are appropriated by Congress for the specific purpose.

A department which will have to account to Congress for its postage bill is going to scan its mailing lists pretty carefully, thereby reducing the visible supply of kindling. The mere act of affixing stamps to envelopes will produce a psychological reaction provocative of real economy because everybody naturally hates to expend stamps, and it will supply accurate data on the total cost of a given publication. Of course the big saving comes from the coincident reduction in paper, printing and clerical expenses not to speak of the tremendous sums annually paid for the transportation of thousands of tons of franked government mail.

---

### Hygiene's Past Successes Prophecy Future Victories

IT IS now more than forty years since Carlos Finlay attributed the spread of yellow fever to the mosquito. It is almost twenty-two years since Reed and his co-workers confirmed that hypothesis. It is a trifle over twenty-one years since Gorgas undertook the application of this knowledge to the eradication of the disease from Havana.

Fifteen years ago (1907) the disease which for more than two centuries had made frequent incursions along our Atlantic and Gulf Coasts with enormous losses of life and treasure, was present in Mexico, Guatemala, Nicaragua, Costa Rica, Colombia, Ecuador, Venezuela, Brazil, Cuba, Barbadoes and Trinidad. During the year 1921, it was present in Mexico, British Honduras, Peru and Brazil. The total number of reported cases in these countries last year did not equal what would have been considered a small outbreak a decade ago. The disease has been stamped out in Peru. It is being actively combated in Mexico and British Honduras. In a few years yellow fever will be a pathological curiosity.

The methods of fighting it have been marvel-

ously simplified. In the earlier days, it was hard to get away from the patient and much effort was expended in the fumigation of presumably infected premises, in the hospitalization and screening of the sick and in the observation of persons theoretically exposed to the infection. These things, desirable though they are from the view point of curative medicine, have been found to be epidemiological niceties so far as eradication operations are concerned and the campaign of today is focused on the control of the breeding of the insect vector, the *Aedes*. When these are reduced to a sufficiently low index, the disease perforce ceases since there are not enough mosquitoes left to bite infectious patients and subsequently to transfer the disease to non-immunes. Since yellow fever is now immediately attacked along these lines as soon as the first case is reported, it is snuffed out before it has a chance to spread to new territory, hence its distribution area has been contracted to such an extent that in a short time the jaundiced handmaiden of death will be as extinct as the passenger pigeon.

As the crowning touch to the solution of this great sanitary problem comes the work of Noguchi. Sternberg's X bacillus, Sanerelli's *Bacillus icteroides*, the *Myrococcidium stegomyiae* of Parker, Beyer and Pothier and Seidelin's *Paraplasma flavigenins* each occupied the stage for a short time as possible causative agents of yellow fever only to be discountenanced and retired to obscurity. Stimson's modest observation of the *Spirochacte interrogans* went almost unnoticed and was wellnigh forgotten until recently when Noguchi announced its probable identity with the *Leptospira icteroides*.

After all these disappointments, the sanitary world has been a little chary of accepting too readily that organism as the cause of yellow fever but certainly the evidence brought forward by Noguchi is extremely suggestive. He has worked out in careful detail the morphological, staining, and cultural peculiarities of this extremely delicate parasite; he has tested out its resistance to heat, desiccation, putrefaction, and disinfectants; he has reproduced the symptom-complex of yellow fever by its inoculation into guinea pigs; he has transmitted the disease from guinea pig to guinea pig by the bite of the female *Aedes*; he has demonstrated Pfeiffer's reaction to the organism with the serum of yellow fever convalescents and has developed a polyvalent serum for the cure of the disease and a vaccine for its prophylaxis. The results already obtained in the treatment and prevention of yellow fever by these are in the highest degree encouraging.

Think what this means! In less than a quarter of a century a pestilence has been stayed to the

saving of thousands of lives and untold millions of dollars and vast territories have been freed of a disease which prevented the exploitation and colonization of some of the richest portions of the globe. The creation and operation of the Panama Canal has been made possible and travel once fraught with greatest risk has been made safe and easy.

Best of all, this is only the beginning of what research and sanitary science are going to accomplish. It is no vain prophecy that many of the diseases which at present shorten the average life-span and cause tremendous losses to society to the hindrance of the advancement of the human race, will one day be eradicated. Already, the incidence of typhoid fever has been marvelously decreased, the tuberculosis death rate is falling and cancer shows evidence of decline. Social hygiene, child hygiene and industrial hygiene are increasing longevity and diminishing morbidity. There is an enormous work, ahead in the control of the sputum-borne infections; there are still almost wholly unexplored realms of disease awaiting conquest but that the mind of man will solve these problems one by one there can be no doubt.

---

THE initial appearance in January of the *Journal of Metabolic Research* is to be regarded not merely as another adventure in scientific journalism, but as constituting an important laboratory news service to a special field, and an interesting experiment in scientific collaboration. Physiological studies alone do not explain the intricacies of assimilation, the work of the chemical laboratory is required, and additional information from the rather widely separated fields of morphology, general biology, pathology, and several departments of medicine. The *Journal* plans to tell the whole story and Frederick M. Allen, as editor, collaborating with something like fifty representative research workers in their several fields, will bring out earlier than has been possible heretofore, and in better sequence, such studies as may be counted distinct contributions in metabolic study. The magazine will serve equally well laboratory or clinical investigators and promises to assist materially in the development of this scientific field.

---

THE scattered publication of articles having to do with occupational therapy has made it so difficult to keep in touch with the rapidly accumulating literature in this field that great interest attaches to the appearance of the *Archives of Occupational Therapy* as the organ of the American Occupational Therapy Association

and the official channel for the publication of materials of fundamental importance in this special field. If occupational therapy is to achieve a definite scientific basis it will be through sifting the best practice to find what is most applicable, the crafts to find what is most useful, and workers to find who is most discriminating. The leaders in this special field are represented on the editorial staff, which includes such authoritative workers as Professor Jules Amar, Laboratoire de Physiologie, Paris, France; Dr. R. Tait McKenzie, University of Pennsylvania; Dr. Herbert J. Hall, President, American Occupational Therapy Association; Dr. G. Canby Robinson, Johns Hopkins University; Norman L. Burnette, Canadian National Committee for Mental Hygiene; and Dr. R. Tunstall Taylor, of the University of Maryland. The Journal is edited by William R. Dunton, Jr., M.D., of Sheppard and Enoch Pratt Hospital, Towson, Md.

---

A NATION-WIDE campaign in the interest of physical training in youth as a means of promoting disciplined leadership in later years is the avowed objective of the effort of the National Physical Education Service to secure the passage of the Fess-Capper bill for universal physical education. Under this Act Federal aid would be extended to any state which developed a state-wide program of physical education and which within a period of five years undertook to provide physical education for every child from the age of six to the age of sixteen years. The Act would be administered by a division of physical education within the Bureau of Education. Provision is made under the same bill to devote the sum of two hundred thousand dollars annually to the use of the United States Public Health Service in making "studies, investigations, and demonstrations relating to the health of children of school age, and the sanitation of school buildings, equipment, and grounds."

Whatever may be the existing differences of opinion in the ranks of educators as to manner and method, whatever variations mark the numerous cults, all are able to argue and are willing to admit the advantages of universal physical education. Children must not only be allowed the time to grow up, but must receive the training that will enable them to develop their full physical and mental stature. Certainly they cannot be expected to develop those muscular coordinations which spell efficiency and health and are so closely related to mental reactions without carefully planned and consistently enforced physical training. Good bodily mechanics are indispensable to good health and are closely related to mental efficiency.

## A Neglected Phase of Workmen's Compensation

BY E. H. LEWINSKI-CORWIN, EXECUTIVE SECRETARY, NEW YORK ACADEMY OF MEDICINE, NEW YORK CITY

IN THE last decade we have witnessed in the United States a phenomenal extension of legislation for compensation against industrial accidents. Ten years ago a bitter controversy was raging around the desirability, practicability and constitutionality of workmen's compensation laws; the proponents were exaggerating the benefits that would flow from the enactment of such laws; and the opponents were likewise vociferous in pointing out the dire consequences that would follow the adoption of such paternalistic and socialistic measures.

After ten years of experience with this form of social provision, it is safe to say that workmen's compensation legislation has been a success, although the diminution of the accident rate which was predicted to follow has not materialized in many industries, and the sustenance provided for the families of the injured has not been sufficient to replace fully the economic loss. On the other hand, neither has malingering become rampant, nor has industry been crushed by the added weight put upon it by the insurance cost.<sup>1</sup>

When it had been shown that American industry on the average kills three men every hour of the year, and that each year about seven hundred thousand become disabled for at least four weeks, society was moved to the quick. In the laws enacted as a result of these disclosures, the stress has been

*The economic folly of elaborate compensation schedules for accidents that could with forethought be prevented finds a parallel in methods of administration which permit injuries to go on to hopeless handicap which scientific care and functional re-education could restore.*

*Service is unlikely to become equalized through uniformity of legislation, but the critical comparison of compensation schedules, the distribution of curative efforts, and the appraisal of end results should make interesting conclusions possible as to the efficacy of the medical methods extant and promote better organization and better work.*

laid on economic relief; and the differentiation of premium rates was relied upon, jointly with the safety movement, to act as a deterrent to the frequency of accident occurrence; very little thought was given at the time to the adequacy of medical provision for the victims of the accidents. As a result, our laws are particularly defective in this regard. With the progress of administration, the lack of original emphasis on the provision for adequate medical attention and of ways and means for securing rapid recuperation and functional re-education of the injured is becoming more evident. There is an imperative need of improving the existing laws in this respect.

The improvement involves changes

all along the line. There should be more liberal provisions as to the amount of medical and nursing care and the period of time the beneficiaries should be entitled to such care; more satisfactory arrangements with the agencies and agents concerned in the treatment and care of the sick, and more competent and vigilant supervision over their work.

In many states, the laws provide for very brief period in which medical attention is to be given; others limit the amount of money to be spent on the case. Some laws allow a free choice of physicians; others limit the injured man in the choice of physician by his employer or insurance company. In some states, there has been worked out a schedule for compensation for injuries and for services of physicians; in others, more elastic arrangements prevail. In some instances the red tape of medical testimony is very onerous to everybody concerned; in others more direct and efficient methods have been adopted. In some states satisfactory arrangements have been made with properly selected institutions for the treatment and functional re-education of the injured; in others, very little has been done in that respect, medical care having been farmed out to some commercial, inadequately equipped agencies. In other words, the technic of administration with regard to the medical features of workmen's compensation is very unsatisfactory. There is need of thoroughgoing study of the problem of administration of the medical benefit in workmen's compensation.

The war has given stimulus to the

2. Public Health Committee of the New York Academy of Medicine: *Medical Aspects of Workmen's Compensation*, *Med. Rec.*, October, 1921.

work of industrial rehabilitation and many states have taken advantage of the congressional appropriation to further the development of vocational re-education of industrial cripples, New Jersey and California having made arrangements with institutions especially devoted to this kind of work. In the state of New York, a special fund has been set aside for the purpose. It is estimated that this fund will eventually amount to more than two hundred thousand dollars, and it is derived from the payments made by the insurance carriers in case of death of a worker without dependents. The law provides that in such instances one thousand be paid by the insurance company, one hundred of which goes to the State Fund, and nine hundred to the special fund for vocational re-education work. Very little, however, has as yet been accomplished along this line. It is a source of surprise that accident insurance

companies, which in most of the states are the main carriers of workmen's compensation insurance, should not have worked out a more adequate system of providing treatment for industrial cripples. They undoubtedly rely on "the law of averages," but the question may be raised with propriety whether the best results have accrued to the injured from the practice of furnishing an "average" good service and accepting the financial risk of carrying the failures to whom the "average" medical service has not proved beneficial. It must be remembered that traumatic surgery has become a distinct specialty requiring special training grounded on an adequate foundation in general surgery, and that provision for physio-therapeutic equipment is essential for a considerable proportion of the injured.<sup>2</sup>

A study of the results obtained in a large number of cases would be of

extreme value to a proper understanding of the present functioning of the workmen's insurance law and would point the way to a needed reorganization. It would give a picture of conditions and lead to important deductions as to the results of medical treatment under various systems of organization. For example, in states where industrial accident work is done by physicians or surgeons employed by the insurance companies or industrial plants, by ordinary practitioners, or by groups of practitioners working as a commercial unit, or by special hospitals, the results could be compared with each other and interesting conclusions reached as to the efficacy of the several methods of providing medical care. Such a study would undoubtedly result in devising rules of procedure which would be of inestimable value to the administrative officers and to the injured workman, now too often neglected.

## Health Problems Involved in Noise and Fatigue\*

### Rhythms, Cadences, Periodicities Regulate Human Activities, but Noise Lessens the Aptitude for Work

BY PROFESSOR HENRY J. SPOONER, M. I. MECH. E., F.G.S., ETC., MEMBER OF THE INTERNATIONAL COMMITTEE ON INDUSTRIAL FATIGUE, LONDON, ENGLAND

I MAY explain that my experience in dealing with fatigue problems has naturally led to my attention being focused day by day on the causes of noises whenever and wherever I have heard them, and on their possible treatment for reduction or elimination. And therefore I may venture to make the following brief remarks on the above classification.

(1) The noise due to traffic in a principal street of a city—such as Cheapside, in the City of London—is so great that the offices along both sides of the street have to be fitted with double sashes to make conversation and mental work possible; with the result that ventilation is bad all the year round, and in the summer the rooms are suffocatingly hot.

(1a) *Noise due to the condition of the roads.*—Main roads, as ordinarily constructed—particularly the asphalt ones—soon get into a faulty condition, the heavy motor traffic causing ruts and holes which have a damaging effect on the vehicles and are the cause of much noise, particularly if the vehicles are badly worn. Rubber roads, if found to be practicable for

heavy traffic, would for important city roads be a perfect solution of the problem; they would be practically noiseless, and would increase the life of all vehicles and of horses using them. Their cost, of course, would be great, but that would probably be a good investment in the case of most of our principal intramural roads, due to the savings on maintenance and sweeping.

A project is afoot in London to make a rubber road around Charing Cross Hospital, at a cost of something less than £10,000. A similar beneficent project for making a rubber road around St. Thomas' Hospital had to be abandoned owing to its cost, but the corridors were laid with rubber as a compromise. Many natives and visitors have appreciated the noiselessness of the Savoy Courtyard, and the entrance to Claridge's Hotel, which are paved with rubber; the present price of which is under a shilling a pound. But when the roads under the hotel archways at Euston Station were paved with rubber some forty years ago, the price was probably twelve times as much. Freedom from noise is worth a great deal, but the question of durability

under heavy traffic has to be decided. The problem is a very important one. On the one hand, the effect of various kinds of vehicles on roads and pavements has to be considered, and, on the other, the effect of roads and pavements on the vehicles. The experiments that have been made by Mr. Arthur Harrison, C.E., on a section of road in Borough High Street, London, laid with rubber-capped blocks, since 1913, with heavy traffic averaging over 190 tons per yard of street width per hour, have been most encouraging. But the evolution of noiseless roads is of course a matter of prolonged research and experiment. The fact is, that the science and practice of road making in this country has not kept pace with the new type of traffic which has come into being during the past twenty years or more. Indeed, the construction and tinkering maintenance of some of our important roads is little short of a scandal. Strangely enough, we have—so far as I am aware—no graduate course in highway engineering in any of our universities comparable with that in Columbia University in the City of New York.

(1b) *Noise due to the working and*

\*Part I of this article was published in the February issue of THE NATION'S HEALTH.

*running of the vehicles on our roads, railroads, and in the tubes.*—A high power, high grade motor car is almost noiseless on ordinary roads; on the other hand, badly worn ones, particularly of the heavy commercial type, also buses and taxis, create a terrible amount of noise, and this is accentuated in the case of motor bicycles when the exhaust cutout is opened, but this should not be allowed except in the open country. Unskillful manipulation of the brakes and clutch of motor vehicles—particularly on hills—is also a cause of much annoying noise.

Even a contractor's cart or wagon, moving at a walking pace, usually makes a great deal of annoying, easily preventable noise, due to the backlash of the wheel hubs on the axle collars.

(1c) *Noise due to the shrieking of railway whistles and to shunting operations, etc.*—The noise due to the exhaust from locomotives and to the blowing off of steam from the safety valves is very annoying, particularly at night, but the shrill, shrieking, ear-splitting railway whistles should not be allowed as they could easily be replaced by low toned ones as used on the Caledonian railway. As the substitution of electric traction for steam traction proceeds, this nuisance will decrease, but electric driven trains are far too noisy, particularly those in our tubes. The noise is bad enough as heard in the carriages, but on the platforms of the carriages where the guards stand, it is simply unbearable; and the jolting, particularly in taking the curves, is so severe that, coupled with the noise, it must be most damaging to the health of the railway men, to say nothing of the passengers. This unsatisfactory condition of things should not be allowed and it is time that public opinion asserted itself. There is also a great deal of preventable noise in shunting operations that calls for attention.

(2a) *Noise due to the running of prime movers.*—In works situated near residential property the installation of prime movers of the explosion type should be avoided, unless they have abnormal foundations, as objectionable earth tremors are transmitted, often to considerable distances. Further, the exhausts of such engines are too often very ineffectively silenced. The almost noiseless electric motor for each main shaft, and for important machines, approaches the ideal, and can often be economically arranged to replace gas engines and steam engines, the

current being supplied from a central power station. Doubtless, in due course, this relatively cheap power will be freely used in mills and factories, to the great advantage of all concerned.

(2b) *Noise due to transmission machinery.*—Usually, there is far too much preventable noise in all transmission machinery, particularly in high-speed belt drives. If a belt has a lap joint, or is jointed by some form of metallic fastener, it is sure to be noisy, and very noisy if there be play in the shaft or spindle bearings. The ideal joint is one of a thickness uniform with that of the belting, such as the joint in Hendry's laminated belting, which gives an almost noiseless drive at all speeds; and the same can be said for the various forms of link belting. There is good scope for further improvements in the direction indicated.

(2c) *Noise due to the working of machines.*—Noise from the working of machines may be due to: (A) The use of a machine that is not the best for the job. (B) The nature of the cutting action. (C) Vibration set up by some unbalanced moving parts.

The noisy typewriters in common use are the bane of business men who have to concentrate their thoughts. The insistent, distracting clatter impairs their power to think clearly and quickly, and has a most fatiguing effect. But, fortunately, the happy substitution of pressure for impact of the type on the paper is the secret of the triumph of the ingenious invention of the silent typewriter.

The above classification suggests the following remarks:

(A) At the recent Efficiency Exhibition held in London, a riveting machine was shown in action, operated by wave power; 2,400 blows a minute were delivered to the work, and the noise was appalling! This was an example of a remarkable invention wrongly applied. On the other hand, we have in the substitution of hydraulic riveting for hand riveting, an ideal example of how to advance from the standpoint of noise elimination—an operation that was so noisy that few boiler riveters escaped deafness by the time they reached middle age, converted into one that is practically noiseless, and also one that produces a perfect job. The substitution of pressure methods for impact ones should be made whenever practicable, in the cause of noise prevention.

(B) The nature of the cutting action in some machines is such that

the elimination of noise is impossible only its reduction being practicable. We have in high-speed circular saws, and in wood planing machines, etc., the most striking examples of this class. The noise from circular saws rapidly increases with their diameter, so that their size should be a minimum for a given job. Wood planing machines and spindle (moulding) machines are notoriously noisy, as they set up far reaching sound waves that have a most damaging effect on the nervous system of people even a good distance away from the machines. The character and intensity of the sound fluctuates considerably, and at times may reach a pitch that is unbearable to some people, and the mental torture is hardly relieved when the strident rolling hum tapers down for a time, as it is followed by dreadful expectancy on the part of the sufferer.

We have paid far too little attention to practical acoustics, and a rich reward awaits the genius who succeeds in suppressing the transmission of such noises; as indeed, it also awaits the genius who can invent some new and noiseless methods of cutting and planing wood.

(C) Apart from vibrations set up by faulty belts, already referred to, any revolving part out of balance causes that part to vibrate. For instance, violent vibrations, due to centrifugal force, are set up by an unbalanced spindle revolving some ten thousand times a minute, even if it be out of balance a few grains only at a radius of one-half inch from the axis. Grinding machines are often noisy, due to vibrations set up by a grinding wheel that has not been balanced; and this can be understood when it is realized that if it is half an ounce out of balance at a radius of three inches, a centrifugal force of five pounds will be set up when the wheel revolves at some 1,900 times a minute, and this would cause objectionable vibrations and noise. Of course, the effects of such vibrations are greatly enhanced when there are worn bearings with consequent backlash, and the spindle or machine is mounted on something that acts as a sounding-board. Fans are often very noisy, for these reasons. Some machines have quick-moving unbalanced reciprocating parts that set up vibrations, with resulting noise. When such parts cannot be easily balanced, the noise can often be greatly reduced by the use of simple rubber shock absorbers and the like. Of course, in some complicated machines it is the aggregation of many little noises that

in their cumulative effect become distressing.

The Blackburn weaving loom is a remarkable machine, but it is safe to say that it has never been designed and constructed from the standpoint of noise. There is a great opportunity for some young engineer to acquire lasting fame and the gratitude of his fellow citizens by silencing this noisy machine, without appreciably increasing its cost.

(3) *Industrial operations in which machinery is not used*—(a) Noise due to the use of hammers and other impact tools used in the operations of the coppersmith, the metal motor body maker and others, can often be much reduced by the use of more rigid support for the work. The fitter's vise is too often fixed on the bench some distance from a support.

(b) Noise due to the handling and transport of materials and work on conveyors and trolleys in shops can often be materially reduced by the use of rubber belts and tires.

(4) *Streets, and the home*.—(a) The noise due to cab whistles, and street calls of itinerant vendors of newspapers and food stuffs, etc., is often very disturbing, and calls for attention. During the war, the use of cab whistles in London was prohibited, and is still prohibited, to the relief of its citizens. Suitable signs, illuminated at night, are exposed at hotels and clubs, etc., when a cab is wanted.

(b) The quietude of the home is often disturbed by the activities in adjacent houses and flats of budding Paderewskis, Carusos and Melbas, and by the frolics of children. There is great scope for improved methods in building construction in the direction of soundproof floors and party-walls.

(c) The chiming of a good set of church bells may be acceptable music to many, but the almost constant ringing and tolling of church bells, that some districts are troubled with, may be a source of great annoyance to not a few, particularly to those whose minds must be kept clear. A case in point may be cited. Once at Warwick, Lord Chief Justice Campbell, irritated by the chimes of a neighboring church, shouted out, "Stop those bells!" suddenly adding, "Unless it be for Divine service, in which case, God forbid."

The crowing of vigorous roosters in saluting the dawn of day in populous districts need not be a nuisance, if boxes or low coops be fitted with proper perches about an inch above the bottom, and if the box or coop is of such a height that the cock can

sleep in a comfortable way in the usual attitude of a perching fowl, but cannot stand upright, there will be no crowing until the birds are let out, for a cock cannot or will not crow unless he can stand up straight with his neck stretched up as far as possible.

This is a typical example of noise prevention, made possible by observing the habits of animals and by the exercise of common sense.

### Detection of Vibration

If there be vibration in running machinery, there is sure to be noise, and vibrations occur when high-speed cranks shafts, etc., are not running dead true. Simple dial instruments are used to detect the slightest wobble in rotating shafts, the magnitude of the error being magnified some thousands of times and indicated by the hand of the dial. But the Fullerton Vibrometer is a beautiful instrument that has a wider range of usefulness in the detection and investigation of vibration of running machinery, such as turbines, dynamos, alternators, and the like. The frequency magnitude and direction of the vibration are indicated, so that information pointing to the cause of vibration is obtained, thus enabling the engineer to eliminate the trouble. The design is based on the tuned vibrating reed principle.

From the standpoint of noise, rubber is an ideal material for floor-covering purposes, and for the treads of stairs, etc. It is noiseless, non-slipping, water and damp proof, durable, and hygienic. And these qualities also make it an excellent material for sole and heel pads. The importance of the use of this valuable material for such purposes to those whose work calls for concentration and freedom from the distracting noise of constant foot traffic, cannot be over-rated.

### Sound and Noise Facts

Unbalanced rotating and reciprocating bodies cause vibrations, and vibrations cause noise. Sounds pass through textile fabrics with great facility, a layer of even thick flannel or baize being found to intercept but a small fraction of the sound from a vibrating reed or buzzer. Sound has been sent through two hundred layers of cotton net, but a single layer of wetted calico was competent to stop it.

Windows rattle when carts pass a house, because glass is sonorous, and air communicates its vibrations to the glass. The window frame being shaken, contributes to the noise, ow-

ing to a vibratory motion communicated to the walls of the house.

Some pieces of the furniture of a house are a little agitated by the approach of a vehicle before we hear the noise it immediately occasions.

Every body which vibrates in the air, throws the air which surrounds it into similar vibrations, which extend outwards from the point of their origin in the form of a sphere.

The blow of a hammer on a wall at the upper part of a high house is heard as if double by a person standing near on the ground, the first sound descending through the wall, and the second through the air.

*Badly proportioned rooms are noisy.* The best proportion from the standpoint of acoustics is a double cube, namely, one whose height and breadth are the same, and are half the length. Probably the next best is one whose height, breadth, and length are in the proportions of one to two to three. With these proportions the reflections of sound as they strike the ear come always at a regular and commensurable intervals, and tend to have a pleasing note or effect. Not so, with badly proportioned rooms, in which the sound pulsations passing and repassing from side to side will very seldom coincide with those passing from end to end, or from floor to ceiling, the result in such cases will be that interference occurs when the sound waves are reflected from the surface of the room, and noise will be audible.

*The transmission of noise in buildings can be reduced.* Continuous beams conduct noise. Girders, beams, or joists should not run through a partition or party-wall, so that one unbroken piece lies under the floors of two adjoining rooms or shops. A single girder has been known in this way to convey noise from one side of a seemingly impenetrable wall to the other.

Various expedients employed for the purpose of *deadening sound transmitted through partition walls* are based on the fact that every change of medium resists the progress of the sound waves. Thus in a partition wall in which the space between the laths or canvas is filled with shavings or sawdust, we have (1) the air on one side of the wall, (2) the paper, plaster, and laths, (3) the sawdust or shavings, (4) the laths, plaster, and paper again; and every change of medium resists the sound waves.

Noise is often a nuisance. In a legal sense, nuisances are of two kinds, namely, (1) Nuisances at Common Law. (2) Nuisances under the

Public Health Acts, commonly called "Statutory Nuisances."

*Nuisance in English law* is either public or private. A *public or common nuisance* is defined by Mr. Justice Stephen as, "an act not warranted by law, or an omission to discharge a legal duty, which act or omission obstructs or causes inconvenience or damage to the public in the exercise of rights common to all his majesty's subjects."

A *common nuisance* is punishable as a misdemeanor at common law. It is no defense for a master or employee that a nuisance is caused by the acts of his servants, if such acts are within the scope of their employment, even though such acts are done without his knowledge and contrary to his orders. Nor is it a defense that the nuisance has been in existence for a great length of time, for no lapse of time will legitimate a public nuisance.

A *private nuisance* is an act of omission which causes inconvenience or damage to a private person, and is left to be re-dressed by action. It is not easy to define what amount of infringement of the rights of property will give a right of action. There must be some sensible diminution of these rights affecting the value or convenience of the property. "The real question in all cases is the question of fact, whether the *annoyance* is such as materially interferes with the ordinary comfort of human existence." (Lord Romily in *Crump v. Lambert*, 1867.)

*Private nuisances injurious to health*, may be summarily suppressed on application to the magistrates, under the Nuisances Removal and Diseases Acts.

### Conclusion

In all civilized countries man has too long suffered from the tyranny of noise, and nothing short of rebellion against it is likely to ameliorate his lot. We may energize in forwarding the cause until we have enlisted the goodwill of a large body of industrialists and others, but even that would not improve matters much within a reasonable time, as the masses are always decades behind the times in matters relating to efficiency; or as Burke aptly stated it, "I have constantly observed, that the generality of people are fifty years at least, behind in their politics."

Manufacturers and others should realize that noise prevention and reduction is a paying proposition, as there are many cases on record of material increases of output occurring

when a change from noise to comparative quietness has been made, even when such changes have been made subject to duress.

Only active propaganda is likely to accelerate the movement, and we venture to suggest that special attention be called for on the annual observance of Fatigue Elimination Day—the first Monday in December—for noise in its cumulative effects probably represents one of the most active causes of fatigue, and therefore one of our greatest wastes, as human resources are the foundation of a nation's wealth. Indeed, we should bear in mind Beecher's dictum, that "little wastes in a great establishment constantly occurring, may defeat the energies of a mighty capital," and tackle the problem of noise prevention in the spirit of Lord Palmerston, who said, "Show me a practical improvement, and that improvement I will do my best to realize."

As you may be aware, the first Monday in December is "*Fatigue Elimination Day*." This movement against the human waste due to avoidable fatigue—initiated by Gilbreth in America many years ago, and by myself in England in 1917—means that each one of us is called upon to consider seriously at odd moments during Fatigue Day what can be

done to reduce or eliminate avoidable fatigue. In 1921 attention was concentrated on avoidable *NOISE* in the shops, in order to help in the suppression of its tyranny. That there should be a standard limit of permissible noise, which, if exceeded, should be a legal offense, all will agree; but I fear we shall continue to suffer until we have influenced public opinion. There is a wide field open for genius and research in the solution of noise problems. A silent typewriter has been produced, why not a silent weaving loom? Weaving, said to be invented by Semiramis some 2,700 years ago, is one of man's oldest industries, but it was not until 1807 that steam was used to drive the power-loom and some seventy years have passed since William Dickinson gave the Blackburn Loom the form it has retained for so many years. And in recent years we have seen the birth of the automatic loom; it now remains for some young engineer to silence these noisy machines without appreciably increasing their cost. Consider seriously what can be done in your immediate surroundings to reduce or eliminate avoidable noise in street and factory so that at the end of every working day there may be less fatigue, and better ability to enjoy well earned recreation and repose.

### Flu Fighters Again Mobilize

Page boys at the Savoy Hotel, London, in their daily "gargle brigade," which looks more like a musical comedy chorus. The ex-sergeant major is the leader of the brigade, which is designed for the protection of both the staff and the hotel patrons against the influenza epidemic. Available vaccines are of value in preventing complications, but prophylactic measures must be relied upon to ward off attacks of influenza. Insufflation is thought to be a better prophylaxis than gargling.

# The Incompetent Heart and Industrial Accident\*

## In Secondary Cardiac Symptoms the Priority of Disease Conditions Should Always Be Considered

BY WILLIAM H. HOLMES, M.D., CHICAGO, ILLINOIS

THE operation of the Workmen's Compensation Law, designed originally to protect the rights and interests of injured employees, has in not a few cases resulted in the filing of fraudulent claims for compensation on the grounds of cardiac disease alleged to be due to injury. As the provisions of the law become more generally known, the number of fraudulent claims may be expected to increase, especially during periods of industrial and economic depression. It is very important, therefore, that physicians, who are brought into such close relations with the compensation law should be alive to the necessity of insuring justice without encouraging fraud.

This article does not include a consideration of disturbances in rate, rhythm, or of functional disease, because the boundaries of our knowledge in these particular fields are constantly being extended. Our knowledge of the organic condition referred to by some as "cardiac failure" and by others as "cardiac decompensation" is more definitely settled, although here, too, the cautious weighing of evidence is necessary if false interpretation is to be avoided.

Decompensation is understood to refer to a condition of circulatory failure as a result of an insufficiency of the muscular power of the heart. Before undertaking a discussion of the cause of this condition referable to myocardial enfeeblement, it seems advisable to review briefly the physiology of the normal heart during muscular exercise, since this has a direct bearing on the question of whether decompensation can be caused by injury.

The ability of the skeletal muscles to perform work is dependent, among other things, on their supply of nutritive substances, including oxygen, and the speedy removal from them of the metabolic products formed. Failure to maintain an adequate oxygen supply results in the accumulation of acid products which tax the mechanism responsible for the maintenance of the neutrality of the blood and

tissue, and gives rise to the symptoms of fatigue. The proper regulation of oxygen supply and the elimination of volatile metabolites is dependent on the extent and character of respiratory and cardiac adjustments to exercise. The respiratory response consists of a greater pulmonary ventilation, to the end that the arterial blood leaving the lungs may be as fully or almost as fully saturated with oxygen as during rest. It is accomplished by an increase in the rate and depth of breathing as a result of medullary stimulation by carbon dioxide certainly and possibly by other metabolic products.

The cardiac response to exercise consists of an increased output per beat, and per minute, to the end that the additional oxygen required and rendered available by the increased pulmonary ventilation may be transported to the contracting skeletal muscles. It is accomplished by an increase in cardiac rate and by a physiologic dilatation which apparently is limited only by the size of the pericardial sac. The rate of the blood flow throughout the body is dependent on the cardiac rate, force, output, venous return, and other circulatory adjustments that, among other things, permit the withdrawal of blood from the splanchnic area where it is not needed, to augment the amount required by the contracting muscles. Under ordinary conditions of life the normal heart uses but a small fraction of its total available energy. The balance of unused power is held in reserve to meet the unusual and extraordinary demands which accompany strenuous or prolonged physical effort. This reserve muscular power constitutes a factor of safety for use in emergency only. That this is true is indicated by the rapidity with which the heart returns to its ordinary state as soon as the need for increased power has ceased.

### A Test of Physical Fitness

This fact constitutes the basis for the various physical tests for determining the functional capacity of the heart. In the British and American armies the pulse rate, rhythm, and the systolic and diastolic blood pressures

were observed in the dorsal position before and after a measured amount of work consisting of hopping one hundred times on one foot. Normally this exercise produces: (1) An increase in the rate and depth of respiration; (2) an acceleration of pulse rate; (3) an increase in systolic blood pressure with a smaller increase of diastolic pressure; (4) vasomotor phenomena; (5) an increase in the intensity of cardiac tones; and, finally, (6) various subjective sensations.

After two minutes rest in the dorsal position the normal heart returns to its pre-exercise rate; rapid breathing ceases; blood pressure begins to decline; the vasomotor phenomena disappear; and the patient is no longer conscious of either respiratory or cardiac action. The application of the exercise test to various forms of cardiac disease including myocardial enfeeblement is accompanied by respiratory and circulatory distress and a slow return to the pre-exercise rate and rhythm. It may cause the production of murmurs, measurable cardiac enlargement, arrhythmia, falling blood pressure, or a disturbance in the relations between systolic and diastolic pressure, persistent dyspnea, chest pain, etc., when decompensation is imminent. Decompensation of the heart begins at the time when symptoms of distress appear during ordinary effort and is complete when the cardiac muscle is unable to maintain the circulation during the rest. It may appear gradually or suddenly, but whether slowly or suddenly it is indicative of pre-existent disease when caused by ordinary effort. It is characterized by symptoms referable to the respiratory, circulatory, renal, gastro-intestinal and nervous systems. Among these symptoms may be mentioned, cough, dyspnea, spitting of blood, chronic bronchitis, anorexia, epigastric discomfort, oliguria, headache, vertigo, drowsiness, irritability, etc.

Physical examination reveals a heart enlarged transversely, with a diffuse, displaced, and feeble apex beat, frustrate beats, impaired tones, valvular murmurs, cyanosis, edema,

\*Read before the International Association of Accident Boards and Commissions, Chicago, September 19-22, 1921.

ascites, albuminuria, pulsating jugular veins, enlarged pulsating tender liver, etc. Neither all the symptoms nor all the signs will be present in every case. Auricular fibrillation is one of the most constant signs.

In the reaction to exercise then we possess a simple logical and easily performed test of cardiac efficiency. The wide latitude of reaction possessed by the normal heart and the readiness with which it recuperates from fatigue leads to the present belief that fatigue alone does not cause failure of a normal heart. The diseased heart enjoys no such distinction and may show signs of decompensation following causes which appear trivial. It is the progressively increasing severity of symptoms produced by gradually decreasing amounts of physical effort, that constitutes cardiac failure. As already stated, it is a condition secondary to myocardial disease, that in nearly all cases can be traced to the effects of either infection, toxemia, mechanical defects or a combination of causes. It is, therefore, to the interests of the employer, the employee, and society at large, to have a record of the patient's history and a careful physical examination as one of the conditions of employment. The discovery of cardiac disease need not debar a man from employment but should constitute a reason for placing him in a position where his disability will not be increased by industry. Having been placed he should be given re-examinations at intervals.

Owing to the fact that serious organic disease of the heart may exist over a long period of time without the presence of striking symptoms, the physical examination of a large group of workmen under the present methods of employment will reveal some whose hearts show evidence of disease.

There will be some whose myocardium has suffered from the effects of infection, or from the toxemia of goiter. There will be some whose myocardium or heart valves are, or have been recently, the seat of an infective process with the organisms still present and viable but temporarily inactive; some whose hearts are handicapped in the discharge of their functions by healed valvular lesions; some whose myocardium, coronary vessels, or valvular orifices present evidence of luetic infection. There will be a few senile hearts and a few fatty hearts and, finally, there will be some that show evidence of arterio-capillary fibrosis with or without signs of renal disease. Such

cases constitute a liability to industry, since, unless they are properly placed, the nature of their employment may serve to aggravate the cardiac disease. In a discussion of the relation of cardiac decompensation to industrial injury, one should, therefore, not lose sight of the fact that several distinct forms of asymptomatic cardiac disease may have antedated the accident. The existence of prior disease does not, however, materially affect the liability of the employer, except in certain cases where it can be demonstrated that cardiac failure was imminent in any event. Cardiac failure might be considered as imminent if with known disease, arrhythmia, dyspnea, or edema had appeared and become progressively more severe over a period of days or weeks prior to the injury.

### Malign Influence

The means by which industrial injury may result in heart failure: An accident may have a malign influence on the heart in many different ways. In some of these the connection is so direct and apparent that there can be little room for differences of opinion. It is hardly necessary to indicate that liability would have to be admitted for cardiac disease following direct injury of the heart muscle, valves, or pericardium, from stab wounds, the penetration of missiles, or injury by the jagged ends of fractured ribs. Where chest injury has resulted in either pulmonary, pleural or mediastinal disease followed by direct extension to the heart the liability would be equally clear. Pulmonary consolidation following injury would constitute clear liability for the subsequent appearance of cardiac disease. A powerful blow over the heart might rupture a valve or damage or rupture the cardiac muscle or disorganize the neuromuscular regulatory mechanism of rate and rhythm. If disease was already present these effects might follow an injury without there being any external evidence. If the cardiac disease is advanced the blow need not necessarily be directly over the heart. Immediate death from reflex stoppage of the heart has been observed too frequently following such trivial injury as is associated with pleural puncture to make this an impossibility. A blow over the heart might result in the loosening of vegetations which being swept into the blood stream would become emboli, giving rise to symptoms in other organs. The influence of a blow in the production of cardiac disease in a

previously normal heart could only be determined by a consideration of the amount of violence applied, by the character of the symptoms and signs, and by their suddenness of onset. In other words, the influence of a blow in the production of cardiac disease can only be determined when the sequence of symptoms is considered in connection with the antecedents of a specific case.

Very frequently physical strain forms the basis of claims for compensation. Here, the strain must be of such a nature as to be considered unusual or excessive for that individual. The carrying of one hundred pounds of brick by a hod-carrier could not be considered excessive. Such exercise constitutes his means of livelihood. If he has followed this occupation for some time his circulatory system is properly adjusted to discharge its functions without undue strain. On the other hand, a similar feat performed by an individual unaccustomed to such effort would be an excessive strain and might result in permanent damage. The existence of cardiac disease predisposes to failure as the result of strain. A teamster fell from the seat of his wagon and sustained severe bruises of the face, hands, and legs. He did not have to struggle to arise, nor was it necessary for him to lift parts of the wagon or its contents from his body. He fell and was bruised and for this condition he received treatment for nine weeks. At the end of this time he returned to work and worked for two weeks. Following his return to work he complained of fatigue, shortness of breath, irregular heart action and swelling of the feet. At the time of the examination some weeks later he was intensely dyspneic, the extremities were edematous, the abdomen contained fluid, the liver was enlarged and pulsating, the heart was enlarged transversely, a systolic murmur was present at the apex, there was auricular fibrillation, albumin and casts were present in the urine. In short, the picture was one of complete cardiac failure. He claimed and received compensation on the ground that the fall had injured his heart. In this he was in error. There were no cardiac symptoms during his nine weeks of treatment. They only appeared after his return to work and showed a progressive increase in severity during two weeks. What were the true facts? He was fifty-seven years old. He had been an alcoholic. There was a history of frequent nocturnal urination for sev-

eral years past. He had always performed heavy manual labor.

Contrary to the belief of many, diseased cardiac muscle is not always benefited by rest. Much in the same manner as the tone of the skeletal muscles is kept up by exercise so the tone of the cardiac muscle is benefited by a moderate amount of daily exercise.

In the case under consideration the demands of the heart during the nine weeks in bed permitted a sufficient loss of tone, so that his return to work constituted excessive strain. A more gradual resumption of activity might have entirely avoided cardiac failure, prolonged invalidism, and expensive litigation.

#### Associated with Infection

Injury may be responsible for severe and permanent cardiac damage by reason of complications. A cut finger followed by a cellulitis of the arm may result in the occurrence of either mural or endocardial infection in a previously normal heart. It is not even necessary that a hematogenous invasion by virulent streptococci occur, since a low grade localized staphylococcal infection of bone or deep tissues with persistent fever and toxemia may result in myocardial degeneration.

Barringer in numerous articles expresses the opinion that cardiac failure in previously well compensated hearts, is more frequently associated with infection than with strain. Severe hemorrhage, traumatic shock, embolism of the pulmonary capillaries by droplets of fat as the result of fractures of the long bones, may all serve to render the myocardium unable to discharge its function. The rôle of mental shock, fear, worry, and other powerful emotions in the production of hyperthyroidism, or rather their rôle in bringing out the symptoms of the disease is not yet clear. If it can be shown beyond doubt that hyperthyroidism followed an injury then myocardial degeneration could be attributed to the same cause since the two conditions are usually associated. In this connection it should be mentioned that thyroid extract is available over the drug store counter without prescription. Its uses and actions are known to many lay persons through the syndicated medical articles in the daily press. The use of drugs to obtain exemption from military service has been reported from many countries. Military surgeons are constantly alert for evidence of malingerers as a means of avoiding serv-

ice or for the purposes of collecting government compensation. In certain industrial cases where suspicion of the genuineness of the disability is entertained the patient should be placed under observation in a hospital, preferably in seclusion.

In conclusion, I believe that it is both fair and keeping with accepted teaching to state that despite the numerous ways in which trauma might affect a heart, infection, lues, arteriosclerosis, and renal disease are the common causes of cardiac disease. Injury may act as a contributory cause of cardiac failure in the presence of known cardiac disease. A negative history has no value in drawing conclusions as to whether disease existed prior to the trauma. A man may suffer from an advanced hypertrophy of the heart due to an aortic regurgitation and yet be able

to successfully carry on his work and present the outward appearance of perfect health. A positive history of repeated attacks of rheumatism, sore throats, chorea, etc., is extremely suggestive of pre-existent cardiac disease.

If the lesion be aortic, syphilis should be excluded by the proper serologic tests. Arteriosclerosis, hypertension, and chronic renal disease should be excluded before attributing cardiac disease to an accident.

If edema, cyanosis, enlargement of the liver, pulsating jugular veins, hypertrophy of the heart are present, they speak for the long standing nature of the condition. If a leukocytosis and fever exist without evidence of infection which can be attributed to the injury, they should be given due consideration in determining the cause of cardiac failure.

## Patrick's Social Reconstruction

THE "Psychology of Social Reconstruction" by G. T. W. Patrick is a criticism of current programs for extensive social reconstruction on the ground of their failure to take full account of psychological factors; it is an interpretation of such plans "in the light of recent psychological studies—particularly studies in certain forms of instinctive behavior."

The proposed reforms are political and economic, the author argues, whereas "life is determined by a great mass of inherited instincts, interests, and passions." The goal of social reconstruction should be the adaptation of the social order to the people who are to live in it. Men change slowly, while society develops rapid changes in organization, and the result is maladjustment. The proposed social reforms exaggerate the situation by abrupt efforts to adapt a new social order to man as he has existed for centuries. The citizens for the new society are lacking, declares the author, because "human beings will not serve." The proposed future is declared, for present day human beings, to be "drab and uninteresting" and devoid of romance because it is built upon a pleasure economy, whereas man has struggled up through a pain economy. Long periods of education are needed to revise the instincts of man to fit the new order.

The discussion of the psychology of work adds to the limited literature of the vast subject of instincts in industry. The brief argument in this

book shatters the idea that man loves to work and that he will be happy with short hours and good pay. The practices of efficiency experts to get the interest of workers by organization fare no better, because work in which the creative instinct of man has no part becomes drudgery. The future of industry depends upon giving an opportunity for the "instinct of workmanship." Industrial partnership is therefore favored. The author gives a hopeful view by pointing out that a large part of our workers will have an opportunity for the development of the creative instinct.

The book should have a wide influence because of its simplicity, directness, and incisiveness of statement. In reading it, one is reminded of one of the sayings of Mr. Dooley—in substance that a man who would promise to teach lobsters to fly in a month would be called a lunatic and be locked up, but the man who expects that people will be made good by an election is called a reformer and remains at large.

The book errs in painting the deficiencies of social reconstruction plans too luridly. By no means do all plans so completely ignore the psychological factor. Practical social reformers have studied social behavior much more than is implied in this book. Even the politician is noted for crude, but effectual, understanding of people. However, the need is great, and an overstatement may draw attention where a precise analysis would fail.

Houghton, Mifflin Company, New York, 1920.

# The Treatment of Carbon Monoxid Poisoning\*

BY R. R. SAYERS, P.A. SURGEON, AND H. R. O'BRIEN (R), UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

CARBON monoxid poisoning is one of the most widely distributed and most frequent of industrial accidents. The gas is a product of incomplete combustion and is without color, odor, or taste; therefore, its presence is frequently unsuspected in many places where it exists. It is an ever present danger about blast and coke furnaces and foundries. It may be found in a building having a leaky furnace or chimney or a gas stove without flue connection, such as a tenement, tailor shop, or boarding house. Hospitals receive a great number of victims of poisoning, whether by accident or in an attempt at suicide, from artificial illuminating gas. People may be affected by leaks wherever water gas is formed or used. The exhaust gases of gasoline automobiles contain from 4 to 12 per cent of carbon monoxid, and in closed garages men are not infrequently found dead beside a running motor. A similar danger may arise from gasoline engines in launches. The gas is formed also in stoker rooms, in gun turrets on battleships, in petroleum refineries, and in the Lablanc soda process in cement and brick plants. In underground work carbon monoxid may appear as the result of shot firing, mine explosions, or mine fires, or in tunnels from an automobile exhaust or from coal or oil burning locomotives.

## The Unsatisfied Atom

Carbon monoxid exerts its extremely dangerous action on the body by displacing oxygen from its combination with hemoglobin. Hemoglobin is the coloring matter of the blood which normally absorbs oxygen from the air in the lungs and delivers it to the different tissues of the body, which need it to do their work. The affinity of carbon monoxid for hemoglobin is about three hundred times that of oxygen. Because of this, even when only a small amount of the poisonous gas is present in the air breathed into the lungs, much of the hemoglobin is locked up in combination with carbon monoxid and so cannot keep up its usual work of carrying oxygen to the tissues. These, due to lack of oxygen, cannot do their work properly. If they are smothered long enough, degeneration sets in,

and the damage sometimes cannot be repaired, even though the patient may not lose his life. It is possible that carbon monoxid has a specific poisonous action on some tissues of the body, especially those of the nervous system, but there is little evidence in favor of this and much against it. Haggard and Henderson found that there was no change in the rate of growth of chick brain tissue, even when it was exposed to an atmosphere containing over 70 per cent of carbon monoxid, and it has been shown many times that animals without red blood (hemoglobin) live in atmospheres containing high concentrations without apparent harmful effects. Recently this was demonstrated at the Pittsburgh experiment station when some roaches were kept for several days in an atmosphere of more than 60 per cent carbon monoxid and 20 per cent oxygen without lessening their activities.

## The Suffocation Syndrome

The victim of acute carbon monoxid poisoning usually experiences the following symptoms: Yawning, sleepiness, tiredness, and a tight-stretched-skin feeling across the forehead; a frontal headache, dull and intermittent at first, later more severe and continuous; this headache is replaced or masked by a typical one at the base and back of the skull, which causes the sufferer to hold his head as far back as possible in an effort to obtain relief; dizziness, nausea (feeling of sickness), and lassitude also occur. The pulse is at first normal, but later becomes full and rapid, the skin flushed, the respiration becomes more rapid with exposure to the gas and, later, irregular. If the exposure is sufficiently long or the concentration sufficiently great, confusion and unconsciousness develop. As the victim recovers, he remains weak for some time; this is especially true of the muscles of his legs. The headache, sometimes very severe, confusion, and partial loss of memory accompany recovery but pass off in time. The nausea may be sufficient to produce vomiting. All the symptoms are accentuated by exercise, eating, and stimulants. When a man is overcome by large concentrations, the symptoms follow each other rapidly and he may quickly fall unconscious. The rate at which a man is overcome

and the sequence in which the symptoms appear depend on several factors: the concentration of the gas, the extent to which he is exerting himself, the state of his health and individual predisposition, and the temperature, humidity, and air movement to which he is exposed. Exercise, high temperature, and great humidity, with no air movement, tend to increase respiration and heart rate and, consequently, result in more rapid absorption of carbon monoxid.

In a chronic form, carbon monoxid poisoning produces a tired feeling, headaches, nausea, palpitation of the heart, sleeplessness, and sometimes mental dullness. Some people develop a "tolerance" for carbon monoxid and may after a while be able to "stand" more of the gas than when first exposed to it. In the treatment of the chronic form of poisoning the most important factor is the removal of the patient from further exposure to carbon monoxid, and thorough rest. Though there are probably many more cases of the chronic form than are usually recognized, it is in the treatment of the acute form that interest is generally centered.

The first and most important thing in caring for a case of acute carbon monoxid poisoning is to get the poison out of the blood. Every moment that it shuts the oxygen out of the hemoglobin adds to the chances of failure of respiration and the heart. Every minute that the tissues are supplied with only a part of the oxygen they need increases the danger of their degeneration and permanent damage. Both to save life itself and to prevent ill health in the future, it is of vital importance to eliminate carbon monoxid from the blood as rapidly as possible.

Oxygen takes the place of carbon monoxid in the blood when the proportion of oxygen in the lungs is overwhelmingly greater. The speed of the change depends on the relative amounts of the two gases in the lungs and on the depth and frequency of breathing. The first step is to get the victim away from the atmosphere of carbon monoxid which he is breathing; the next is to supply him with oxygen. This may be done by getting the patient into fresh air, but only one-fifth of air is oxygen. If a tank of pure oxygen is available, it is far better to use it as the action is much

\*By permission of the Director of the Bureau of Mines.

To use the Bureau of Mines oxygen inhalator (in conjunction with Schaefer manual method of inducing respiration): Open valve of oxygen bottle, and, as soon as oxygen reservoir is fully inflated, adjust face mask over patient's nose and mouth, securing same in place by means of head cap. Then continue artificial respiration, which should be interrupted no longer than absolutely necessary.\* A fully charged bottle (150 atm.) will last thirty-five minutes.

faster and the after-effects, especially the headaches, are much less severe and not so prolonged. The oxygen should, if possible, be given through an inhalator made similar to an anesthetic mask or Tissot Army face mask, which can be fastened over the patient's mouth, nose, or entire face. If an inhalator is not at hand, a physician may give oxygen through a nasal catheter. In the absence of any of these accessories it can be sprayed directly from the tank about the patient's face. It should be started as soon as he is removed from the carbon monoxid or before, if possible, and should be kept up for at least twenty minutes.

It may be that when the victim is found his breathing has stopped, or is very weak and irregular. In this case one of the rescuers should begin at once artificial respiration, by the Schaefer method.

Place the person' on his abdomen; remove from his mouth all foreign bodies, such as false teeth, tobacco, and gum; see that the tongue is forward; turn his head to one side and rest it on his forearm, so that the mouth and nose will not come in contact with the ground, and extend the other arm forward. If the person is thin, prepare a pad of folded clothing, or blankets and place it under the lower part of his chest. Do not make this pad too thick. Do not wait to loosen the victim's clothing but begin artificial respiration without delay. An assistant may remove all tight clothing from the victim's neck, chest, and waist, and place blankets, hot water bottles, safety lamps, or hot bricks, well wrapped in paper or cloth, about the person.

Kneel, straddling the person's thighs

and facing his head; the palms of the hands are placed over the short ribs with the thumbs parallel with the spine about two inches apart and the fingers spread out as much as possible, the ends of the little fingers reaching just below the last rib; with arms held straight, swing forward slowly so that the weight of the body is gradually brought to bear on the person. This operation, which should take about two seconds, must not be violent, lest the internal organs be injured. The lower part of the chest and also the abdomen are thus compressed and air is forced out of the lungs. Now, immediately swing back slowly to remove the pressure, but leave the hands in place. Through their elasticity the patient's chest walls expand and his lungs are thus supplied with fresh air. After two seconds swing forward again and repeat deliberately about fifteen times a minute.

Continue if necessary for at least three hours without interruption, or until natural breathing has been restored or a physician has arrived. Even after natural breathing begins, carefully watch that it continues. If it stops, start artificial respiration again.

While the administration of oxygen is by far the most important factor in the treatment and cannot be over-emphasized, other things should be done to help the patient. He should be kept quiet and lying flat, to help his weakened heart. As he gets better, he should never be allowed to walk about or in any way exert himself, for there is danger of heart failure. Heat from safety lamps, hot water bottles, or warm bricks, rubbing the arms and legs, and keeping the patient well covered with blankets all help the circulation, and aid in tiding the body over a period of low

vitality. The safety lamps, hot bricks, etc., should be well wrapped in cloth or paper as a precaution against burning the patient. Other stimulants, such as hypodermics of caffeine-sodium benzoate or camphor in oil, may be used only by a doctor, and after he has considered the possibility of over-stimulation and consequent collapse. The patient should be kept in bed for a day at least. Later he should be treated as a convalescent, being given plenty of time to rest and recuperate. Just how long this should be depends on the severity of his poisoning and should be decided by his physician.

#### Summary of Treatment

(1) Administer oxygen as quickly as possible, and in as pure a form as is obtainable, preferably from a cylinder of oxygen through an inhalator mask.

(2) Remove from atmosphere containing carbon monoxid.

(3) If breathing is feeble, at once start artificial respiration by the prone method.

(4) Keep the victim flat, quiet, and warm.

(5) Afterward give plenty of rest.

#### Sanitation of Water Supply

Modern methods of water supply and purification are the subjects of a very pertinent article by M. F. Sanborn, in a recent issue of *The American City*. The requirements of water, the uses to which it is put, and its purity for domestic uses are discussed by the writer. Some industries need water with certain characteristics, and must employ special treatment to obtain it. The water used for other public purposes than drinking does not need to be of such high standards.

Water is purified or partially purified by plain sedimentation, chemical precipitation, aëration, slow filtration, disinfection, water softening and treatment with copper sulphate to kill algae, diatoms, etc.

Sedimentation with the aid of chemicals is used with turbid and colored waters, especially as a preliminary treatment for rapid sand filtration, in which case the preliminary sedimentation extends somewhat the interval of time between filter cleanings.

Aëration of some waters is of benefit in increasing dissolved oxygen and reducing carbonic gas. It also removes to a large degree the odors caused by stagnation of that water which is drawn from below the zone of rapid change of temperature.

# Interest and Distinction in Utilitarian Buildings\*

## The Gold Medal Group for Industrial Design at the Recent National Architectural Exhibition

BY GEORGE C. NIMMONS, ARCHITECT, CHICAGO, ILLINOIS

**P**UBLIC interest at the completion of the construction of an important group of buildings usually centers around the answers to such questions as: What is their construction and how long did it take to erect them? Why are the buildings arranged as they are? Why do they look as they do? How is the mail order business of Sears, Roebuck & Co. conducted in these buildings, and how is it possible to operate economically and successfully over such vast areas of floor space?

The Philadelphia store is the latest of several erected by Sears, Roebuck & Co., at important distributing centers. Philadelphia was selected as the most advantageous site for prompt and economical delivery of goods to customers in the eastern territory, and for the additional reason of relieving the Chicago store of the congestion arising from increased business.

### Basis of Problem

The principal requirements which

\*At the National Architectural Exhibition in Washington, D. C., last May, held by the American Institute of Architects in connection with its annual convention, the gold medal for industrial design was awarded to George C. Nimmons & Co. on the strength of the design for the Eastern Store of Sears, Roebuck & Co. The distinctive features are embodied in the structural units, rather than to applied ornament. We are publishing this description through the courtesy of The Architectural Record.

formed the basis of the problem to be solved were:

(1) Buildings to accommodate at first an annual business of fifty million dollars, with complete provisions for greatly increasing this capacity in the future.

(2) The proper location of the buildings on the site, consisting of forty acres with proper railroad connections.

(3) The adoption of the most economical fireproof construction and the determination of a plan, arrangement, and design for the buildings best suited for the most direct and efficient handling of goods.

(4) A simple inexpensive treatment of the exterior of the buildings that would meet with the approval of the owners and which would be appropriate and attractive enough, in the opinion of the Philadelphia Art Commission, to occupy this site on one of the city's most important boulevards.

(5) Proper provisions for the health, comfort, and welfare of the employees.

(6) And, finally, the very important requirement of including in the new store all of those features and improvements that had proved most successful in the old stores and the omission of all those which were un-

successful or which had become obsolete.

The plant consists of the merchandise building with a ground area of 119,000 square feet, basement, and nine stories, in which all the goods are handled, an office building of 31,650 square feet ground area, six stories and basement, and a power plant of 19,270 square feet ground area. In addition to this there are other minor buildings of no special interest.

The frontage of the buildings on the boulevard is 780 linear feet, and the aggregate floor area of all stories in the main building is 1,592,500 square feet, and their cubical contents 22,088,101 cubic feet.

The foundations consist of 529 concrete caissons down to rock, supporting 4,766 concrete columns in the different stories, making a total length if placed end to end of thirteen miles. There were nine million brick used, 138 thousand barrels of cement and eight and one-half million pounds of reinforcing steel.

The type of construction is strictly fireproof throughout. The cantilever flat slab system of reinforced concrete was employed in the floors and columns; the walls were of common brick, faced with dark red face brick and trimmed with gray terra cotta

General view from Roosevelt Boulevard. The buttress construction of the Gothic is here appropriately adapted to modern industrial use.

which has blue backgrounds where ornaments occur. Wooden window frames with sliding sash were installed, except where fireproof ones were required, because of the ease with which they can be opened for ventilation and cleaning, and their greater freedom from cracks and openings which admit dust and cold draughts. The columns are spaced twenty feet apart each way and carry a live load of two hundred pounds per square foot on the floors of the merchandise building, and a lighter load in the office building. This uniform spacing of columns, both ways, is economical in construction and also makes it possible to change fixtures and equipment in the buildings from any pair of columns to any other pair without cutting or alteration. . . .

The mail order business is merchandising on a large scale; sales are made exclusively through the medium of catalogues circulated among the customers, who order from these catalogues by mail.

To the farmer or dweller in the small town or village the business offers advantages and conveniences similar to those offered by the modern department store to the residents of large cities. About ninety per cent of the orders can be delivered to his door by parcel post.

The business of one of these plants consists of receiving the letter orders from customers, which come every day by the truck load, gathered up from the different depots in mail sacks. The letters are opened usually by machinery by the hundred. They are then read and indexed, and tickets are made out for all goods to be shipped; these tickets are sent by pneumatic tubes to the proper departments. On the tickets so made out, are indicated the departments which handle those goods, the route and manner of their shipment and further, this very significant thing—the exact time at which each article is to arrive in the shipping room. This important feature in the handling of goods, prevents unnecessary congestion and results in distributing the handling of orders evenly over the entire period of the working day. The operation of the plant therefore becomes a uniform, steady activity which brings about maximum efficiency while at the same time preventing spasmodic speeding up.

The transmitting of orders from the departments to the shipping room is largely mechanical. If it were not, the mail order business could

not be conducted in these large buildings over such vast areas of space without causing great delay in shipment and largely increased cost in handling.

The mechanical means employed for filling orders of customers, in a general way are as follows: When a ticket calling for goods to be shipped arrives through the pneumatic tubes in any department, the goods are taken out of stock and delivered to the nearest spiral chute. These goods, except the very large ones slide round and round in their descent in these spiral chutes until they are discharged at the bottom onto the conveyor belts, which take them to the sorting aisles. They are sorted several times in a very simple way which results finally in their arriving at the particular rack where

obviating the necessity of going through the city post office at this end of the shipment. Large or heavy articles go by freight or express.

This system of handling goods by means of conveyors, chutes, etc., was the chief factor which had to be taken into account in planning the merchandise building; in studying the arrangement and plan of the entire group of buildings, this building was the most important one and its requirements had first to be provided.

After considering the different ways in which the four big rooms of this building could be arranged it was decided to put them together in a "U" shape plan, as this gave the shipping room the most central location for direct action of the conveyor belts, also the best lighting for the rooms and the most advantageous ar-

The tower that dominates the group is not for its ornamental effect at all, but to meet the very essential requirement of providing a place for the sprinkler tanks.

goods for the customer are assembled, as they arrive from the different departments of the store.

When all of the goods for any one of the customers have arrived in the various receiving racks made for that purpose, they are gathered together and packed in a bundle or box. The Post Office Department maintains a post office in the plant which furnishes canceled stamps to be affixed to the packages on the spot, thereby

arrangement for future extensions.

The office building was placed on the right so as to give the clerical employees the view and good light of the boulevard; besides, this situation is a convenient present location and will also be a central one when additions to the plant are completed.

One feature of particular importance in the plan of this building was the placing of elevators, stairs, toilets, etc., in the rear of the center,

so as to have uninterrupted light space for office use for the entire remaining area of the building. This is a distinct advantage, because the office space may then be divided or the whole space may be used as a single unit, as traveling belts and conveyors may extend through the entire length without interruption.

The power house provides heat and light, power for all mechanical ventilation, elevators, pumps and the pneumatic tube system, refrigeration for the drinking water circulated through the store, and for the kitchen cold storage. Space was provided in the building for the additional equipment needed for future additions. At present there are installed six 500-horsepower return tube boilers with complete mechanical stokers and mechanical means of handling coal and ashes. All discarded boxes and wooden crates are ground up in what is called the "Hog Machine Room," adjoining the basement of the merchandise building and blown back through a pipe to the boilers and consumed without further handling, as fuel.

In the engine room there are now installed one 125, one 350, and one 750 kilowatt generators, and one 1,500 kilowatt turbine driven generator. All of the buildings have mechanical ventilation by which washed fresh air is provided for the different parts of the buildings according to the number of people occupying them. Each toilet fixture is also individually ventilated. All pipes, wires and conduits are run underground from the power house in a system of underground tunnels to the merchandise and office buildings.

The remaining question proposed for an answer was: Why do the buildings look as they do? The feature which dominates the group is the tower, and that should be accounted for first. The reason for this tower is not at all, in the first instance, for its ornamental effect, but for the very essential requirement of providing a place for the sprinkler tanks. A low rate of insurance can be secured only when a building is sprinkled and in this case the lowest rate given for this class of building was granted by the insurance authorities, all possible safeguards against fire having been provided.

Although the insurance underwriters do not require the water tanks to be enclosed like these in this tower, they do require that they shall contain a certain amount of water, be placed on a certain height above the

The women's rest room of the Eastern Store of Sears, Roebuck & Co., Philadelphia. The welfare of the employes is given the most serious attention. The Chicago store of this company has reported a decrease of 50 per cent in labor turnover directly to be attributed to personal service work among their employes.

buildings, and be protected against freezing. In this case there were required four nine thousand-gallon pressure tanks and one eighty thousand-gallon gravity tank. Inasmuch as these tanks, with their enormous weight of water, had to be supported by heavy, fireproof construction, the additional expense of enclosing their supports in four walls where they extended above the roof, and thereby making a fourteen story tower at the main entrance, was relatively small compared with the benefits secured in increased office space, saving in maintenance of the tanks, and in the appearance of the whole group of buildings.

The dominating tower has a very essential function to perform besides being a clock tower and an ornamental feature to the façade. Had these tanks been left exposed above the buildings, as they generally are, they would have been so prominent and so ugly in the long distance views from the Boulevard that they would have seriously damaged the fine appearance of the whole group of buildings.

The next most noticeable feature of the exterior is that the great wall surfaces are broken by pilasters which appear like buttresses between the windows. The reason for their presence is that it was desirable to keep the inside of the walls as free as possible from large projections of columns or piers, so as not to interfere with desks, benches, and equipment which were to be placed next to the windows. The columns, therefore, which form the skeleton structure of the outside walls were made to project on the outside of the walls instead of the inside. As these col-

umns grow smaller as they extend upward the natural form to give them was that of a buttress.

### Old Art in New Design

If one is not trying to invent a new style of architecture, the obvious thing to do at this stage of the design is to select that style which seems best suited for expressing the structure. As there was no reason structurally or otherwise for a large cornice or for carrying through strongly marked horizontal features and as the walls would be much more economically built by terminating them with a simple coping than with a cornice, the choice of a style naturally fell to the Gothic. While they had no industrial building such as big mail order houses in the Middle Ages, and while reinforced concrete was never even heard of, their buttress construction is correctly expressive of the construction of these buildings, the use of their wall copings are just as appropriate and their pointed arches just as applicable as round ones. This style of the Middle Ages was therefore employed and the result is Gothic architecture applied to a group of modern industrial buildings, or "Industrial Gothic," as some have applied the term.

In applying this style of architecture, no effort was made to find ready made features in old Gothic buildings and plaster them on wherever they would stick. On the contrary, an effort was made to mold the important parts of the buildings into shapes harmonious with this style, and to flavor the detail with a distinct feeling of modernity.

Terra cotta window sills and lintels

(which had to be there for any kind of design), are employed in such a manner as to divide the building into pleasing proportions. Gothic tracery enriched with color is utilized in the terra cotta spandrels and entrance panels in such a way as to give interesting prominence to these features. The colors employed were gray for the tracery, blue for its openings or backgrounds, and dark grayish red for the brick.

### The Human Interest

In conclusion, a brief description is given of the organization which operates this plant and the provisions for welfare work for the employees.

As soon as a decision was made to build this plant, work was started on selecting and building up an organization to run it. Shortly before the buildings were completed, about two hundred experienced men and women arrived from the other plants, mostly from the main plant at Chicago. These formed the nucleus of the new organization.

New employees were taken on as fast as they could be trained and assigned to their positions. The plant started to ship goods October 18, 1920, with about two thousand employees, a number materially increased by this date.

The welfare of the employees has always been given the most careful consideration by this firm at all of their plants. In an article in the *Architectural Record* for June, 1919, on the subject of "Employees' Welfare Work," a description was given of a decrease of 50 per cent in labor turnover at the Chicago store of Sears, Roebuck & Co., attributed to the personal service work done there for their employees.

At the Philadelphia store the same policy has been pursued. The offices and working spaces are all well lighted and ventilated, and are in every case clean, attractive and sanitary places, well adapted for the work to be done. In the office building there is a restaurant and cafeteria supplied by a kitchen, up-to-date in all its equipment, where lunches of clean, wholesome food are served at cost price. There are a smoking room for men and a rest room for women, and also a piano and phonographs for entertainment and dancing.

On the first floor there is a completely equipped doctor's office with physicians and nurses in charge, which takes care not only of accidents and illness, but also carries on a system of examination and care

of employees that endeavors to prevent sickness.

When the weather is favorable, employees are encouraged to seek the outdoors for their noon hour, where

an athletic field is provided for outdoor sports, and where there are also pleasant walks among the flowers, shrubs and trees, with which the grounds are landscaped.

## Standards in Industrial Ventilation

THE National Safety Council has prepared a statement of the general requirements of industrial ventilation, together with such arguments for its maintenance as will appeal to employers and to the man on the job and such instructions as will serve to direct measures for the achievement of satisfactory air conditions. Six simple measures are suggested in order to get good ventilation in the workshop: (1) Keep the temperature right, that is, from 60 to 68 degrees F. (2) Maintain the proper relation of humidity to temperature. (3) Remove gases, fumes, and dusts at their source. (4) When dependence is placed upon window ventilation, all windows are to be opened slightly. (5) Prevent drafts at windows by the proper placing of window shields or deflectors. (6) Open all windows and doors for a short time at night, on Sundays, and perhaps at noon.

### Necessity for Ventilation

Ventilation is accomplished by stirring up or replacing the air in an enclosed space. When a space is first enclosed, the confined air is as healthful as outside air. Soon, however, conditions may render the confined air unhealthful. Deterioration in such air includes: (1) An increase of carbon dioxide; (2) a decrease of oxygen—not harmful; (3) an increase or decrease of moisture; (4) an increase in temperature; (5) the addition of objectionable dust, fumes, or vapors; (6) the addition of bacteria; (7) the addition of odors; (8) the stagnation of air surrounding the bodies of persons. These changes are in turn caused by artificial illumination by means of open flames, etc., by manufacturing processes, and by the presence of human beings.

### Increase in Temperature

Excessive heat, although it does not materially affect the chemical properties of the air, if maintained for too long a time, causes fatigue, lowers the vitality, and makes workers more susceptible to sickness and disease. It also lessens the general inclination to work. An investigation conducted by the New York State Ventilation Commission showed that a temperature of 75 degrees F. reduced production

as much as 17 per cent; while 85 degrees F. caused a 37 per cent reduction. Generally speaking, the following are the most healthful temperatures for workrooms: 60 degrees to 64 degrees F. where the employees are doing work that requires strenuous physical exertion; 64 degrees to 66 degrees where there is an average amount of physical exertion; 66 to 68 degrees where the work is comparatively light; it is advisable never to have the temperature exceed 70 degrees. Temperature in this country is usually measured by the ordinary Fahrenheit thermometer; special thermographs may be used for automatically recording the temperature of rooms.

### Changes in Humidity

The air in a plant or an office may be at exactly the proper temperature and yet be quite uncomfortable because it is too dry or too moist. If outside air at winter temperature is heated to room temperature, and if no moisture is added, it feels uncomfortably dry and cold due to the fact that too little moisture in the air causes an excessive and unnatural evaporation of moisture from the skin. The temperature of the skin is therefore lowered and under such conditions one feels several degrees cooler than the temperature indicated by the thermometer. A person living or working in a room at 68 degrees temperature often feels cold and thinks the temperature should be raised; whereas the air really needs not more heat, but more moisture.

To overcome this, people in steam-heated buildings often put a small cup or pan full of water on the radiator, which may evaporate a pint of water per day. This is an effort in the right direction, but it is pitifully inadequate. As a matter of fact, when ordinary winter air at 20 degrees is heated to 68 degrees, it is necessary to evaporate approximately 522 quarts of water each day for every one hundred thousand cubic feet of air space that is occupied eight hours a day. One large company has reported to the National Safety Council that an arrangement for introducing steam directly into the room is the only practical device which will supply suf-

ficient moisture to the air. Air washers, used in connection with the plenum system of ventilation, can also be regulated to humidify the air.

The amount of moisture in the air is generally measured in terms of "relative humidity." For each degree of temperature, there is a certain maximum amount of moisture that can be contained in a cubic foot of air. The hotter the air, the more moisture it will contain. The ratio between the amount of moisture actually present in a cubic foot of air, and the maximum amount which can be contained at that temperature is called the relative humidity. There is a certain range of relative humidity for each degree of temperature which is just right for comfort.

Presence of bacteria in the air is another untoward condition. Bacteria cause sickness and disease and every precaution should be taken to avoid their presence in the air. The number and variety of bacteria will need to be determined by standard methods of air analysis and such measures as may be necessary employed to control them.

#### Addition of Odors

Odors in themselves may be quite harmless but may be of great importance as an index of air contamination. Perfectly harmless odors, however, may be so disagreeable that it is inadvisable for persons to continue work where they are present. Deodorants are often used, but it should be remembered that they merely mask offensive odors and should seldom be used alone. It is generally advisable to use disinfectants which will destroy the bacteria which may be responsible for the disagreeable odors, or to provide proper ventilation for their removal. The determination of odors depends almost entirely upon the keenness of smell of the investigator.

#### Air Becomes Stagnant

When a person remains quite still for some length of time in a room where the air is not in motion, a thin film of impure air forms about his body and keeps from him the purer air that fills the rest of the room. This can be prevented by stirring up the air with a local fan or by using some other method of ventilation.

Ventilation can be secured through:

- (1) Spontaneous ventilation;
- (2) windows;
- (3) doors and transoms;
- (4) elevator shafts;
- (5) stairwells and courts;
- (6) special openings;
- (7) cowls and roof ventilators;
- (8) special ventilation ducts;
- (9) vacuum ventilation;
- (10) plenum ventilation;

or through (11) combined methods. Not all of these methods, however, are equally effectual, and great care must be exercised in selecting a method for any specific condition. Expert advice may be necessary in properly selecting, installing, and operating a ventilation system.

#### Means of Ventilation

By means of diffusion and because of wind, a certain amount of air is able to enter a room through the pores in building materials and through the cracks and crevices at doors, window frames, and other places in the walls, floors, and roof. This is especially noticeably in buildings of flimsy construction but spontaneous ventilation can hardly be relied upon to give complete satisfaction in modern office or factory buildings.

Many factories depend more upon open windows for their ventilation than upon any other device. Windows pivoted at the center are considered better for this purpose than the ordinary type of vertically or horizontally sliding windows, for they permit the entire space to be opened, while the latter type opens up only half of the window space. They also take greater advantage of any wind that may be stirring and can be used to control the force and direction of the incoming air.

One of the chief difficulties in window ventilation is encountered in the effort to avoid drafts. This trouble may be overcome in part by installing a medium grade of light colored muslin in place of the glass in the lower pane of an ordinary window or in a frame about twelve inches wide inserted below the lower sash. If this muslin is renewed at frequent intervals it will permit the entrance of fresh air and will not materially decrease the light. Drafts may also be avoided to some extent by placing a deflector vertically or at an angle on the lower sill and another deflector at the top of the upper sash. Window ventilation is most likely to be satisfactory if *ALL* windows are open a little at both top and bottom; they should be opened slightly on the side from which the wind is blowing, and wider on the other sides.

Windows as ventilators are sometimes not entirely satisfactory, for their success depends largely upon the men who regulate their opening and closing. Then, too, in summer, when the temperature of the inside and outside air is nearly equal, little or no movement of air through the window obtains unless there is some wind. In winter, most workers do not want the windows open because they allow the

entrance of air that is too cold. This latter objection may be overcome by installing long radiators directly under the window. In some installations metal ducts lead the incoming air through the radiators.

Doors help to change the air in work rooms, depending upon how often they are opened and closed and where they lead. Transoms installed over doors also assist in introducing fresh air into places where it is needed.

Elevator shafts that are open at each floor often play an important part in ventilating certain rooms or buildings. A great amount of air is displayed by the rapid ascent and descent of an elevator, and it may be advisable to provide an opening to the outside air at both the top and bottom of the shaft, though there may be an objection to such an arrangement because an open elevator shaft in case of fire may act as a chimney and spread the flames. Automatic fire doors, however, installed at all openings in the shaft may counteract this objection.

Stairwells and courts, if open to the outside air at the top and bottom, assist in securing proper ventilation. They are, however, subject to the same objections as are open elevator shafts, and automatic fire-door protection at all openings is advisable. It has been found that a suction fan installed at the top of a stairwell is effective in drawing air into rooms which open into the stairwell. When such installations are made, means should be provided for emergency or automatic shut down of the fan in case of fire.

In some rooms ventilation is secured by providing openings for this special purpose. Usually the outlet is at the top of the room; the best position for inlets is about five feet high; or, if the air is warmed, they may be placed just above the floor.

If there are openings in the roof for ventilation purposes, special precautions must be taken to prevent the entrance of rain. One way to do this is to install weatherproof hoods. Various types of hoods, sometimes called cowls, roof ventilators, etc., are on the market, and for some of these devices, the manufacturers claim additional advantages. Some ventilators are open on all sides, while others controlled by the wind, discharge air only in the direction in which the wind is blowing. One type has a gravity damper which can be operated manually, or in case of fire it will be closed automatically by the melting of a fusible link.

In some factories it is advisable to install special ducts, tubes, flues, or chimneys to carry off the air, fumes, gases, or dusts. The air can be moved through these ducts forcibly by the action of fans. If the air is heated purposely, or in the manufacturing process, it may rise through the ducts without the action of a fan. Some manufacturers place a small steam coil or an open flame in the duct to assist the movement of air; others liberate a small stream of compressed air or steam in the duct in the direction in which the air is to be moved. Some types of cowls or roof ventilators are so designed that with wind blowing through or around them, there is a certain amount of suction created in the ducts to which they are connected.

### The Function of Fans

Many people think that the only function of an office or desk fan is to help keep cool the occupants of the room where the fan is operating. Fans, however, perform in addition the important function of stirring up the air and preventing stagnant areas in occupied rooms where there are liable to be heat and moisture accumulation. Merely to keep the air stirred up is one form of ventilation. This method will not remove impurities from vitiated air, nor will it supply pure air but power driven fans placed in the open room increase very materially the comfort of the workers.

The vacuum system of ventilation provides for drawing (aspirating or exhausting) the air from a room by means of a fan. No vacuum is actually formed, however, for air enters the room through the windows, doors, and other openings.

### General Vacuum System

There are two types of vacuum ventilation: the general and the local. The former provides for the placing of a fan at a window or at some other opening in the wall and blowing the air from the room directly to the outside of the building without using any ducts or tubes. This method involves low initial cost and comparatively low cost of maintenance and may be especially satisfactory in laundries, foundries, and other places where there is a great amount of heat and where large quantities of steam, gas, or fumes are present.

The local system of vacuum ventilation—often called exhaust ventilation—requires the installation of hoods for collecting the air, gas, fumes, or dust, to be removed, a fan, and metal tubes or ducts for conveying this air to the outside atmosphere or to come prop-

erly provided place for disposal. If properly designed and operated, this system can be installed to remove objectionable gas, fumes, or dust at the exact point of origin.

### Plenum Ventilation

With the plenum system of ventilation, air is driven or propelled into the room by fans. This method does not remove bad air from the room, but dilutes and mixes it so thoroughly with fresh air from the outside that under normal conditions the results from a ventilation point of view are quite satisfactory.

Fans for plenum ventilation may be placed at windows or at other openings in the wall so as to drive fresh air directly into the room, or one large fan may be installed at a remote point and blow fresh air through ducts into a number of rooms. The latter type of installation, though involving a higher initial cost and greater cost of maintenance, has many advantages that cannot be secured in other types of ventilating systems. It not only permits of exact measurement and regulation of the quantity of air admitted, but also makes it possible to change its quality by properly washing, humidifying, heating, or cooling the air before it is distributed.

Incoming air can be cleaned either by filtering or by washing. Filtering is usually done through cloth which should be cleaned at frequent intervals so it will not become clogged and prevent the passage of air through it.

The washing of air is usually more satisfactory than filtering and can be accomplished by passing it horizontally through a closed chamber into which water enters in the form of a spray or water curtain. The water first removes all suspended particles of dirt from the air, after which it may be strained through a fine metal screen and used again. It is surprising to see the amount of dirt that is collected by water after washing a large volume of air; it has the appearance of sewage and is like it in composition.

In many systems, the air washer is used automatically or manually to regulate the humidity of the air that is used for ventilation purposes. The excess water carried from the washer by the air is removed by passing the air over eliminator plates just as it is coming from the washer, and humidification may be provided by heating the air or the water before they enter the washer. The hotter the air or the water, the more water vapor the air will hold; therefore, by regulating the heat of the air or the water, any desired degree of humidity

can be secured. Such control is necessary and is possible only by special systems.

It is possible with the plenum system of ventilation to centralize the heating apparatus and thus do away with many of the radiators and other equipment that are necessary with most other heating systems. A large heater may be installed so as to heat the air as it leaves the washer just before entering the fan. If the heater is arranged in sections, steam may be admitted to as many or as few sections as desired, making possible an absolute automatic or manual temperature control. The temperature can also be controlled by automatically or manually operating an air bypass under or around the heating compartment. Heaters should be so designed that the greatest possible radiating area will be provided consistent with a uniform and maximum velocity of air. Heater manufacturers have developed tables showing heater sizes which depend upon the number of cubic feet of air passing through the heater per minute, and whether low or high pressure steam is used.

In hot weather when it is unnecessary to heat the incoming air, the action of the air washer serves to cool the air to some extent. Further cooling is possible by removing the heating coils and substituting refrigerating coils. This method, however, is very expensive and is seldom employed. A much cheaper way to cool the air used in ventilating is to cool with refrigerating coils the water that is used in the air washer. This latter method is used frequently in banks, theaters, and hospitals.

### Combined Methods Used

There are certain advantages and disadvantages connected with all systems for ventilating and it is quite generally agreed that a combination of two or more methods gives the best results. As a general rule, air should not be removed from a room without providing for the entrance of an equal quantity of fresh air. One combination that is very popular is that of the local vacuum and plenum systems. Air can be cleaned, moistened or dried, heated or cooled, and distributed to the points where it is needed the most, and provision can be made to remove impure air from the exact points of origin.

One important point that is frequently ignored, is that no matter how good a ventilating system is installed, it is often desirable to open all windows and doors at night, on Sundays, and perhaps at noon, to secure as complete a change of air as possible.

# Industry and Preventive Medicine

BY OUR LONDON CORRESPONDENT

THE importance of industrial medical service to the community has not heretofore been appreciated. Previously the public has come into contact with the medical profession only in case of illness. Questions affecting the maintenance of health were impersonal and for the most part were left to public services concerned with the water supply, drainage, etc. The personal note has been sounded in relation to maternity and infant welfare, school medical service, and, more recently, in venereal clinics, but, generally speaking, means had to be found for bringing preventive medicine into direct contact with the adult. For this purpose, said Dr. Edgar Leight Collis, professor of preventive medicine, University of Wales, before a sectional meeting of the British Medical Association recently held in London, industry, which gathered the adults of the community together, has provided the means.

The points, were, whether the community would benefit if industry shouldered the responsibility and whether industry itself would benefit. The benefits of both were closely interlocked. Regarding the health of the industrial population, Army recruiting data showed that only 36 per cent of the male adults were classed Grade 1. The miner and agriculturist provided higher proportions than any other industrial groups. The peculiarities of industrial disease were important in drawing attention to the influence of occupation upon health. Industrial medicine was recognized to be directly aimed at preventing disease and maintaining health. The state was undertaking to bring up to adolescence healthy individuals. Employees must in turn maintain that health.

The state strove to instil the principle of health up to adolescent life. The youth passed into some occupation and found no attention paid to health and its maintenance. There were immense possibilities in industry. A standard set up by the all admired capitalist who ruled industry would spread from the factory to the home. But today the reverse holds good. A long over-due duty was owed to the community by industry. The drift of workmen from one place to another was a heavy economic burden, various calculations placed this turnover in some cases at 400 per cent, an outlay which had been shown to

fall to 30 per cent, where medical supervision of entrants and hygienic conditions existed. Erring in calculation on the safe side, seventy million pounds could be saved a year by adopting these conditions. Much was lost by lost time, either by certified sickness or the conditions of lowered health proceeding sickness. Sixty millions might be obtained by medical supervision in industry. Convalescent workers anxious lest their places should be filled, had their recovery delayed, or had another break-down by commencing work too soon. Convalescence could be expedited both mentally and physically by graduated activity of an interesting nature, and the best form of interest was remuneration for work done which was today precisely the form of activity prohibited for the industrial convalescent.

The Ministry of Pensions had shown what could be done in reeducating maimed soldiers, 80 per cent of whom could be trained to carry on. The need for continuing the work with those maimed while earning a livelihood was clear. The figures serve to demonstrate that industry by developing industrial medicine had the promise of great profit while it fulfilled a great social service.

Professor Collis concluded by pointing out that the trend of thought today was against nationalization of industries, but industries must realize that while maintaining their independence they took over at the same time certain responsibilities as regarded those employed, which under nationalization would be undertaken by the State. Recognition of these responsibilities and taking them up would entrench the position of industrial independence. Failure in this matter, quite apart from economic waste, must sooner or later cause those employed to demand reconstruction of modern industrial organization.

## The Physician to the Plant

Dr. I. M. Legge, of the Factory Department of the British Home Office, while allowing that Dr. Collis made a good point by showing how cheaply preventive industrial medicine and treatment of industrial diseases could be done, nevertheless, thought that before shouldering the burden, would be inclined to point out by another little sum in arithmetic, that a biggish sum has already been paid

out for health insurance the benefit of which might be considered a little dubious. Thus, from a factory employing one thousand men, every year considerably over two thousand pounds (\$6,000) found its way to the panel of doctors probably ignorant of the always interesting work which occupied their patients. Not until the doors of the factory were open to medical men, would there be scope for industrial medicine.

Sir Kenneth Goodby, M.R.C.S. of London, remarked that in certain industries, lead working for instance, doctors were hampered by the goodwill obstruction of employers and employed in efforts to improve their conditions. He dealt at length with lead poisoning, and said that lead operated on the progenitory span of men and women and tended to a reduction in the birth rate. The birth rate for painters was 155, and the general figure was 162. Even the painters were much higher than clergymen, barristers, solicitors, law clerks, farmers, and graziers. The figures showed that the risk must be something more than a question of lead poisoning. Sir Kenneth thought that medical men who were engaged in inquiry should be met not grudgingly, but wholeheartedly by labor. Labor should not regard the statistics by medical men as a sort of opportunity for prying into private life. It was a curious fact that when one began to ask labor for particulars, the first thing one got was a suspicious look and the second was the remark: "Is this for the insurance company?"

Capt. Elliott, M.C., M.P. continuing the discussion said that medical men should be treated by labor, as friends and not as employers' agents, who were only anxious to restore a man's health and send him back to work again. They should remember the intense bitterness and suspicion of Labor in regard to what the working man considered to be an attempt to screw more work out of him for the already insufficient money he was being paid. They might not agree with all these points but that was the working man's way of looking at it; and now at the birth of a new branch of medicine it was important that the correct spirit should be attained.

Capt. Elliott did not agree with the suggestion that laziness was pathological rather than psychological; but he hoped that by further research they would be able to dispel that Monday morning feeling, which many, even medical men, got. With regard to the casualties of industries, he hoped the Section would give the Parliament as

much help as it could on this subject. Money was being paid for this question, but unless they specialized, the scheme of a great organization under the pension schemes would wither and disappear, and the casualties of industry would drift into the unemployable classes.

### Hygienic Measures Extended

In a special address on industrial hygiene Sir Thomas Oliver drew attention to the fact that within the past few years the scope of industrial hygiene had widened. It now included not only consideration of the conditions under which work was carried on, the hours of labor and diseases incidental to occupation, but it dealt with the physical effects of work as seen in fatigue and how hours of work and rest might be correlated so that there might be obtained the maximum of effort, also that the hours of respite from labor might be made sufficiently long for recovery from exhaustion to take place, the tendency had been to remove from labor any serfage element which might have clung to it, a remnant of bygone days, and to recognize that men and women were not mere machines, but that they were entitled to the opportunities for improving themselves mentally and physically. Today industrial hygiene was no longer the affair of one nation but of all of the advanced nations.

The creation of the International Labor Bureau under the auspices of the League of Nations had raised industrial medicine to a higher platform, so that while the health of the workers was one of the main objects, and production was regulated by the physical fitness of the worker and by the hygienic conditions under which labor was carried on, the fact that industrial medicine had become international would incite backward nations to aim at securing a higher standard of health for their work people as well as more efficient means of increasing production. Arising out of legislation passed for improving conditions of labor and shortening the hours of work, and proceeding through the medical supervision of workers and the elimination of the unfit as well as the substitution of comparatively harmless for harmful methods of production of industrial medicine, it might be said that although it had made such rapid strides that many of the results obtained had become fresh energizing influences in the life of nations, yet many opportunities for good still lay in front of it. Medical examination of workers before commencing their industrial career would per-

haps in some instances create hardships, but the ultimate gain would transcend all these. Even with the ordinary precautions taken there would still be found a certain number of persons who would break down in health earlier than others, either as the result of diminished vital resistance or of idiosyncrasy. The speaker dwelt at a very considerable length on lead poisoning and also discussed phosphorus and carbon monoxid poisoning.

### Fatigue Factors

Fatigue was made the subject of lengthy consideration and it was pointed out that the recent war had been followed by disastrous consequences in the case of many of the discharged soldiers. The long weary vigil in the first line of trenches and the hardships endured, also the comparatively idle month spent away from the firing line, had made many of the men unwilling or unable physically to return to their previous employment. Some of them had lost the taste for work, and they clamored, like those who remained at home for shorter hours of labor. Shortening the shifts and a change in the hours of work were notable factors of the times. Men no longer went fasting to work at six o'clock in the morning and breakfasted in the factory at eight. They left home or should, after a comfortable breakfast in time to reach the factory by 7:30 a. m., and as Collis and R. M. Wilson in their writings show, it had been to the advantage of employer and employed. Better time keeping had been the result and there had been less sickness. Shortening of the hours had in most industries been followed not by diminished but by increased production and by a rise in wages, but as there was a limit to which hours could be shortened and production efficiency retained it was a question whether in some trades this limit had not been reached.

Oliver was anxious to ascertain to what extent fatigue was experienced by the female workers. No method of estimating hitherto in vogue, had been quite free from defects, so that the simple method of testing muscular efficiency which he employed was not above cavil. With the ordinary spring dynamometer used in hospital practice for estimating the muscular strength of patients—the hand grip of women was taken by the lady supervisor, A.B.S.C. of a University, before breakfast, before the midday meal and again just before giving up work in the evening. It was to be expected that at the end of a nine

hour shift the instrument would register less than the figure obtained in the earlier hours of the day, and while this was usually the case it was not so in every instance, for on certain occasions, as seen in the school charts, the evening grip registered higher than that of the mornings or midday. Admitting that value of the readings of the dynamometer was diminished by "knack" or the particular manner in which people handled it, yet it could not be said that either the circumstances or habit played any recognizable part in the results obtained. The occasional increase of muscular strength was more frequently observed in women who were employed in such heavy work as shell shifting. He was, however, unable to offer any explanation as to the increased muscular strength at the close of the working day. The speaker concluded by saying that since industrial medicine had come to stay, facilities in the future would have to be provided to medical students and young graduates to become familiar in a practical manner with the objects. Never were the times more opportune than today. The prosperity of a nation was bound up with the health of the people.

Preventive medicine had, he said, practically speaking, swept the British Isles clear of typhoid fever and had considerably reduced the mortality of diphtheria. What it had accomplished on the mortality side of public health it could also accomplish in regard to occupational disease. The die had been cast. There was a psychology of industry just as there was a physiology. Psychology was no longer simply "The Science of Mind or Soul" but the science of the facts of human nature and behavior and there was no department of human activity which offered greater scope for its study and application than industry. Employers no longer regarded "industrial hygiene" as something to be turned down on the ground of its interference with labor, and the conditions under which it was carried on. They recognized that it introduced into industry that something with a touch of humanity in it which softened the asperities of labor, made occupation more healthful and tended to bring employers and employed into closer touch with each other.

National Negro health week will be held April 2-8 at Tuskegee, Alabama, under the auspices of the Tuskegee negro conference and the National Negro Business League in cooperation with the U. S. Public Health Service and similar agencies.

## Recent Compensation Decisions

THE Supreme Court of Illinois, October 22, 1921, reversed a decision of the Industrial Commission holding the Commission's evidence insufficient to prove that the claimant's permanent incapacity for work from heart disease was caused solely by the accident in which his ribs were injured. The facts are stated as follows in the opinion of the Court: The employee, A. R. Mercer, was employed in the mine of the defendant. "On December 31, 1918, as he was getting out of an empty coal car the mule started up, catching him between that car and another car in the region of his left lower ribs. He made application for compensation alleging total and permanent disability."

At the time of the hearing before the arbitrator he was totally and permanently incapacitated for work from heart disease, which was conceded, and the only question in dispute was whether the injury was the proximate cause in whole or in part of his disability. The arbitrator decided that the accident was the cause of the total and permanent disability. . . . On a review of the decision of the arbitrator by the Industrial Commission additional evidence was heard and the award was confirmed. The award was confirmed by the Circuit Court.

The applicant was fifty years old and before the accident had worked on a farm and for four or five months prior to the accident had worked in this coal mine. He had always been able to do such work and testified that he never had any kind of heart trouble or internal trouble before his injury; that at the time of the accident he did not think he was hurt and went back to his work, but could not get his breath and was sent home in a buggy; that a doctor bandaged him, and he had been under the care of that doctor and another since his injury; that his heart ached, his head felt as if it was going to burst, and his heart felt filled up and heavy. The doctor who treated the applicant at the time of the injury and bandaged him and also treated him at different times up to the hearing testified that he was suffering from myocarditis, an organic disease of the heart caused by infection and consisting of degeneration of the heart muscles; that the disease is never the result of an outside injury or force applied to the body; that he had examined the applicant thoroughly since the injury and he was in a bad condition, weak and emaciated, but there were no results remaining from the injury which could possibly cause myocarditis; and that he had a temporary disability only from the injury. The other doctor who had treated the applicant testified that when he saw him after the accident he had received an injury of the left lower ribs which from the nature of the injury appeared to be a light blow; that he had been strapped for the injury and was having considerable trouble with his heart and abnormal respiration, and that the squeezing he had could have aggravated the condition that was already there, but the heart disease was present before the time of the injury. This was all the evidence before the arbitrator and commission and was insufficient to sustain an award that the condition of the applicant was solely the result of the accident.

An employee is entitled to the statute to be compensated for every accidental injury suffered in the course of his employment and arising out of the employment. That is the measure and limit of his right, and if an injury sustained is the proximate cause of the incapacity for which compensation is sought, the previous physical condition of the employee is unimportant, and he may recover for

permanent incapacity which results from an accident independent of pre-existing disease. He is not entitled to compensation for a condition resulting from a pre-existing disease, and from an injury suffered in the course of employment and arising out of it. If there is a pre-existing disease, the employee is entitled to recover for all the consequences attributable to the injury in the acceleration or aggravation of such disease. Such aggravation or acceleration, permanent and progressive in its nature will entitle the employee to compensation to the extent and in the proportion in which the pre-existing disease is increased or aggravated. Mere predisposing physical condition does not affect the right to compensation. If an accident results in a lesion or a new condition of which it is the proximate cause, there may be a recovery of compensation for the same regardless of predisposing conditions making the employee more susceptible to the injury. . . . Under these rules, the previous condition of the applicant was a material circumstance to be considered in ascertaining whatever his condition of total and permanent disability resulted from the accident suffered in the course of his employment and arising out of it or from the disease, and, if from both, the proportion in which the accident contributed."—*Springfield District Coal Mining Co. v. Industrial Commission*, 132 N. E. 752.

THE Appellate Court of Indiana, December 2, 1921, held that a one-eyed employee receiving an injury causing permanent loss of his eye is not entitled to compensation for the total disability under the Workmen's Compensation Act, Sec. 29, and can recover merely for the permanent loss of the sight of one eye, under Section 31, though the loss of his eye resulted in total blindness.—*Stevens v. Marion Machine Foundry & Supply Co.*, 133 N. E. 23.

THE Appellate Court of Indiana, November 18, 1921, has held that a workman doing his work in the normal and regular way and who sustains an inguinal hernia in lifting has sustained "a personal injury by accident" within the Workmen's Compensation Act, such injury being accidental.

It is "sufficient to say that the uncontradicted evidence is that the in-

jured employee immediately after receiving the injury told his foreman about the severity and location of the pain from which he was suffering; that thereupon the foreman sent him to the nurse; and that the nurse, in turn, sent him to the company's surgeon. From all the evidence bearing on this point, the finding is a legitimate conclusion."—*Terre Haute Malleable & Mfg. Co. v. Wehrle*, 132 N. E. 698.

WHERE an epileptic employee hauling water in a tank on which he had to stand while filling it was drowned in the partially filled tank and there was no direct evidence that he fell in as a result of a fit, a finding that the accident arose out of the employment was authorized and not subject to the objection that from the evidence it conclusively appeared that his death was the result of disease, within Workmen's Compensation Act, Sec. 76, Cl. (d).

Whether or not an employee's death was the result of an accident arising out of the employment is a question of fact for the Industrial Board.

Appellants were in the business of threshing wheat and other grain. Steam power was used and appellants had in their employ at the time Carl Beil, whose duty it was to haul water from a nearby reservoir, in a water tank drawn by horses. . . . By the side of the opening and fastened to the top of the tank was a pump. In operating the pump it was necessary for Beil to stand on the top of the tank near the opening. On the morning of June 12, 1919, and a short time after Beil in the course of his employment had gone to get water, the tank partially filled with water, was found at the reservoir, and in the tank was the lifeless body of Beil. The employee who thus lost his life was subject to epilepsy.—*Miller et al v. Beil et al. App. Court of Indiana*, January 28, 1921, 129 N. E. 493.

THE Supreme Court of Iowa, November 22, 1921, upheld a finding of the Industrial Commissioner that hernia in the following case did not arise from a strain during employment:

"It is the plaintiff's claim that, in pursuance of his line of duty in the defendant's service at the stockyards in Sioux City, he was engaged in repairing certain electric wires extending along or over the top of a high board fence. For that purpose he climbed upon the fence, which act was accomplished by reaching his

arms up and over the fence and throwing his leg over the plank at the top. As he made that movement he felt a sharp pain in his right groin, but went on with his work. He had never experienced such pain before, nor had he ever before developed a hernia, and did not at the time realize the nature of his hurt. This incident occurred in September 14, 1916. He did not report the matter to the defendant or consult a physician until October 2, 1916, when he called upon a doctor who discovered a small hernia in the groin and advised the use of a truss. Plaintiff procured a truss and continued to work for defendant as before until February 3, 1917, when he was discharged. He says that after the alleged hurt, and before he applied the truss, he suffered frequent pains at the point, compelling him sometimes to suspend work. His physician testifies that a common immediate cause of such a hernia is a 'strain from exertion or something of that sort.' This witness further says that a man 'might continue at work with a traumatic hernia until several days had gone by.' It is not, he says, an unusual thing for a man to suffer hernia and 'continue at work for a period of several days and put up with the pain. This is true of enough cases to justify the statement.'

"The arbitration committee found that the alleged injury 'did not arise out of, or in the course of, plaintiff's employment' and is not a personal injury within the meaning of the compensation act, and that 'he has not met the requirements of the burden of proof to an extent justifying the award of compensation.'"

This finding was affirmed by the commission and in its opinion the Court says:

We are inclined to the view that the showing made by the plaintiff is sufficiently vague and uncertain to bring the case within the statutory rule which makes the finding of the committee and of the commissioner final upon questions of fact, and such being the situation, the judgment of the district court must be reversed. . . . It is a matter of common knowledge that thousands of men suffer from inguinal hernia, and that many of them are able to point to the time and place where it developed and the physical strain or exertion which occasioned it and yet were never prostrated by it. It is doubtless true that in very many cases the lesion takes place from the gradual enlargement of the inguinal rings, and is not traceable to any accident or unnatural strain or exertion; and that much difficulty exists in determining whether in a given case the hernia, if one is found, is of a compensable character. This difficulty justifies the arbitration committee and the commissioner in closely scrutinizing the testimony and satisfying themselves as nearly as possible as to the origin of the alleged injury in order that they may do equal and exact justice between the parties, but the rule applicable is the same as in other cases and requires only a preponderance of evidence.

—*Bunch v. Sioux City Stockyards Co.*, 185 N. W. 139.

THE Superior Court of California, November 4, 1921, determined that where the employee of a packing plant, engaged in putting grapes into a machine, threw a grape at another employee which hit and injured the eye of a third employee engaged in sweeping the floor, this injury to the third employee was not an injury arising "out of and in the course of the employment" within the Workmen's Compensation Act.—*Federal Mutual Liability Insurance Co. v. Industrial Accident Commission of California*, 201 P. 920.

THE Supreme Court of Colorado, November 7, 1921, upheld the finding of the Industrial Commission that the death of any oxy-acetylene welder by lightning while working on a steel bridge was caused by an accident arising out of his employment within the Workmen's Compensation Act.—*Hassell Iron Works Co. v. Industrial Commission*, 201 P. 894.

IN California, recently, the District Court of Appeal held that a woman who was an inmate of a brothel and was reasonably suspected of having an infectious venereal disease may be quarantined by the health authorities of a city and pursuant thereto kept in custody by the chief of police.—*Ex parte Dayton* 199 P. 548.

### Anthrax in Animal (Horse) Hair

Anthrax has been found at frequent intervals, particularly in horse hair that has been imported. In New York City during the last seventeen months there have been reported to the Division of Industrial Hygiene 34 cases of human anthrax, 11 of which have been fatal. A campaign of education among those engaged in the manufacture of brushes, particularly those using horse hair, was undertaken in order to secure general cooperation in an endeavor to stamp out this industrial and public health menace.

After a careful study the New York City Department of Health adopted special regulations concerning the manufacture and sale of hair brushes and hair cloth.

Primarily anthrax is an animal disease, frequently transmitted to man, not in the sense that the animal is the host, but the animal is the victim

through which man receives the infection. It is widespread in cattle, sheep, and horses, less frequently in man. Experiments in laboratories show that rabbits, mice and guinea pigs are peculiarly susceptible.

Originally, as a source of infection, anthrax was probably telluric, coming to the surface in pasture lands, and through grazing was taken up by animals and disseminated. Lands rich in organic matter seem best suited for the growth of anthrax. Fields may be contaminated through hay or seed from infected areas, or from carcasses of animals not deeply buried, the ground water probably carrying the organisms to the surface. Every object to which anthrax spores can be attached becomes a source of danger and is liable to cause the spread of the disease at any time.

Dr. S. Dana Hubbard writes a monograph on the subject which is published by the Department of Health of the City of New York. He points out among other things the method of prevention, saying that nothing is more important than having workmen provided with and made to use proper appliances, such as gloves, face masks, overalls, which should be cleaned after use. The physician should be on the alert to diagnose the disorder immediately because the earlier the diagnosis the greater the opportunity for success in saving the life of the patient and the prevention of the dissemination of the disease to others.

### Public Health Service to Hold Examination

An examination of candidates for entrance into the regular corps of the U. S. Public Health Service will be held in Chicago April 3, 1922, the Surgeon General's office announces.

Candidates must not be less than twenty-three years nor more than thirty-two, and they must have been graduated in medicine from some reputable medical college, and have had one year's hospital experience or two years in professional practice. They must pass satisfactorily oral, written and clinical tests before a board of medical officers.

Successful candidates will be recommended for appointment by the President with the advice and consent of the Senate.

Requests for information or permission to take this examination should be addressed to the Surgeon General, U. S. Public Health Service Washington, D. C.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Michigan Institutional Health Administration

By RICHARD M. OLIN, M.D., COMMISSIONER, MICHIGAN DEPARTMENT OF HEALTH, LANSING, MICH.

A YEAR ago, one of the inmates—a sometime motor mechanic—armed with a stethoscope, the voice of authority, and a supply of pills, was largely responsible for the health and sanitation of the Michigan Reformatory at Ionia. He was supervised only by the occasional visits of a local physician. The deplorable conditions existing in this institution were brought to the attention of Governor Alexander J. Groesbeck in February, 1921. Governor Groesbeck conducted a thorough investigation and placed the Michigan Department of Health in charge of the medical work and sanitary conditions of the Reformatory.

A complete health survey followed, which included the examination of all the seven hundred Ionia prisoners, together with an exhaustive sanitary inspection by Department of Health sanitary engineers. Such findings as eighty-eight cases of syphilis, most of them untreated, twelve cases of valvular heart disease, and sixteen tuberculous inmates, and a total lack of the most rudimentary hygienic measures rendered the necessity for a thorough clean-up imperative. After the initial survey had been finished, a full-time physician was installed and the necessary supplies and equipment purchased for the dispensary and hospital.

### State Wards are Studied

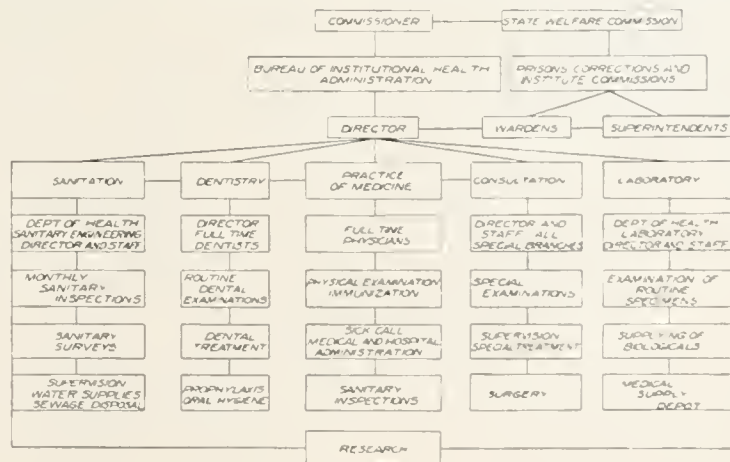

Such was the beginning of the Department's institutional health administration. During the preliminary stages of the work, penal and correctional institution medical records were found to be either lacking or so scanty as to be of little practical value, with the single exception of Jackson Prison. Health surveys of

all institutions were necessary before any intelligent conception could be gained of the medical problems at hand. Surveys, each one of which occupied a group of workers over periods of from three to five weeks were accomplished, the customary procedures consisting of a complete history and physical examination, a blood Wassermann reaction, throat cultures, and re-examination of cases of suspected tuberculosis, valvular heart disease, and other thoracic conditions. In the younger age groups, the Schick test was added, followed by toxin-antitoxin when indicated, and at the Coldwater Public School all the children were given an intradermic tuberculin (Mantoux) reaction. Sanitary inspections, during which the institution was given the most careful scrutiny, formed an important part of each survey. The Ionia Reformatory, the Branch Prison at Marquette, the Industrial School for Girls at Adrian, the Industrial School

for Boys at Lansing, and the State Public School at Coldwater have been examined according to the plan outlined, each inmate coming before the Department's workers at least five times. During these surveys the problem has unfolded itself in a very striking manner.

The State Administrative Board on September 13, 1921, passed a resolution directing this Department to supervise the medical, dental, and sanitary work in all the state penal and correctional institutions and the Coldwater Public School. Advisory supervision of the insane hospitals and other state institutions was also given by this resolution. This discussion is confined to the work in the penal and correctional institutions.

In the background of our plans is the constant endeavor to raise the health of each state ward to the highest possible standard, to cure his disease, to correct his defects, and to make his institutional environment

A graphic illustration of the organization of the Bureau of Institutional Health Administration, headed by Dr. Robert A. Macgregor. The advisory supervision over the health administration of hospitals for the insane is not indicated.

wholesome and physically clean. To this end, a new department bureau has been created—the Bureau of Institutional Health Administration—with Dr. Robert A. Macgregor as its director. Dr. Macgregor has been the physician at the Michigan State Prison at Jackson for several years and is unusually well acquainted with the organization and medical problems of a large prison.

The organization of Dr. Macgregor's bureau is graphically represented on the accompanying chart. (Our advisory supervision over the hospitals for the insane has not been included in the diagram.)

The Bureau office serves as a central clearing station for institutional medical business. In Lansing the following records are filed, kept on a uniform group of forms which were prepared after an exhaustive review of the similar blanks in use throughout the United States:

(1) *Physical Examination*.—A complete history and physical examination on each inmate.

(2) *Daily Report*.—Showing the names, number, and diagnosis of all inmates excused from work on medical grounds, the hospital admissions and discharges, the inmates receiving venereal disease treatment, sanitary inspections, and spaces for miscellaneous information.

(3) *Monthly Reports*.—Showing the number of seriously ill inmates for the month, the number of men received with physical defects, the number of venereal disease treatments given, sanitary measures, consultation, and the transfer of inmates. At monthly intervals, the physicians are asked to furnish us the quantity of food on a certain day, and caloric values per inmate are estimated from this dietary.

A monthly report from the main office of each institution gives the names and numbers of all inmates received and released during that period.

The system of medical records is augmented by a daily sick call card for each inmate, dental cards, a tuberculosis blank, and cards for charting treatment of gonorrhea and syphilis.

From these forms the physical condition of any inmate on admission can be determined at a moment's notice, and changes in his health determined from the tabulated daily reports. When questions of defects or disease arise in connection with the parole of prisoners, the Pardon Commissioner refers the cases to the Bureau of Institutional Health Ad-

Hallway in one of the cell wards at Ionia Reformatory, showing overcrowded conditions and disorder. Entrance to hospital in background.

ministration. Dr. Macgregor reports upon the suitability of the given individual for release from a medical standpoint. Cases of syphilis, for example, are not eligible until they have finished two courses of treatment, and until they are free from open lesions. It is also against the general policy of the Department to recommend an inmate for parole who is suffering from diabetes, tuberculosis, or some other chronic illness, unless death seems imminent, or unless very definite assurance is received from his family that they are willing and financially able to care for the invalid.

Full-time resident physicians have been stationed at four institutions, and plans call for the placing of others in the immediate future. All these doctors are supervised by the Bureau of Institutional Health Administration as far as their purely medical functions are concerned. It is understood that the physician must be answerable to the Warden or Superintendent for his work outside of the practice of medicine, the situation being parallel to the army, where the clinician is responsible to the commanding officer for the fulfillment of other than medical duties.

#### Plan of Administration

By direction of this department, resident physicians hold a daily sick call in all respects similar to the same dispensary practice in government

service. A detailed history is taken on each inmate, and a complete physical examination done at the earliest convenient date after admission. Blood Wassermann reactions and vaccination against smallpox are universal requirements. In the younger groups the Schick test is performed and the positives followed by toxin-antitoxin. The Compiled Laws of Michigan state very plainly the duties of prison physicians in regard to visiting men in punishment, sanitary inspections, and supervision of food supply; and, by order, the physicians strictly enforce these statutes. The various reports compiled by the resident physicians have been previously enumerated.

Detailed supervision of routine and excessive "red tape" have thus far been eliminated as much as possible, it being the belief of the Department that each physician should have the widest possible latitude in his work and that he should be able to express his own individuality to the fullest extent compatible with the Department's conception of his duties and the wishes of his Warden or Superintendent.

A consulting staff has been appointed quite recently. This group is composed of practitioners, men of firmly established reputation in the branches which they represent. A director and several co-workers have been chosen in each of the following specialties: eye, ear, nose and throat, internal medicine, general surgery, orthopedic surgery, dermatology, gynecology and urology. By a resolution of the Administrative Board, these physicians will receive their expenses and an honorarium of fifty dollars for each day spent in the service of the state. For the time being, the specialists are assisting in remedying the large accumulation of existing defects. Fifty-one tonsil and adenoid operations were done at the Coldwater Public School in December, and a series of more than two hundred tonsillectomies at the Industrial School for Boys, Lansing, were performed in January and February. After the correction of existing surgical defects, an orderly service will be established, consultants in all branches of medicine and surgery making institutional visits at stated intervals, and when emergency calls are received.

Laboratory specimens are examined at the Michigan Department of Health Laboratory in Lansing or at the Branch Laboratory in Houghton. Biological products and nearsphenamine have been distributed by the

laboratory for a considerable period, it being much less expensive to buy these materials in large quantities, rather than each institution buying a small amount from the retail market. It was the good fortune of the State Administrative Board to purchase the medical supplies and equipment of Camp Custer, Battle Creek, from the United States Army. This material—some thirty large truckloads comprising a very long list of individual articles—has been placed in charge of the Director of Laboratories. A central medical supply depot has been established from which the several institutions will be able to make requisition for the supplies they require, at prices which are only fractions of present day catalog values.

Dentistry is under the direction of Dr. Kenneth R. Gibson. There are four dentists in the field who visit the various institutions (including the insane hospital group), spending enough time in each one to finish the dental work at hand. Dental record cards and monthly reports are filed in the bureau office. It is eventually the department's wish to station full-time dentists at the larger institutions.

#### Routine Inspection

On his monthly visits, the director makes a sanitary inspection of each institution. In addition, more detailed sanitary surveys are carried out by the State Sanitary Engineer and his staff. Changes in water supply, sewage disposal, and new construction are supervised by the Engineering Bureau.

Next spring the remodeling of an existing building at Ionia as a 120 bed hospital will be undertaken. This building will house tuberculous inmates from all penal and correctional institutions. About seventy-five inmates with active pulmonary tuberculosis are known at this writing. It will also provide facilities for the treatment of cases which cannot be properly handled in the various institutions, and for surgical cases requiring extensive postoperative care.

The fact that no reference has been made to psychiatry or psychology has probably been noticed. Though apparently ignoring the problem, the Department is by no means unaware of its existence, and realizes that any lasting prison reform must include careful studies of the feeble-minded, of the various psychoses, and psychopathic personalities who undoubtedly form over fifty per cent of any state prison's population. Be-

Physician examining one of wards in the Boys' Industrial School, Lansing, Mich.

ginning work of this nature is anticipated, but it has been considered wise to try first making healthy bodies, before undertaking the vastly greater problem of diseased minds.

Institutional health administration is an attempt to give the state wards

of Michigan the best possible medical attention. The chief executives believe that in committing an individual to a penal or correctional institution, the state has assumed a very large responsibility. The Governor appreciates this duty keenly, and he realizes that, aside from giving the inmate a square deal, Michigan will derive benefit from a higher standard of institutional medical work. A healthy inmate is more amenable to discipline while serving his sentence. He is, if paroled, physically well, better equipped for earning an honest living, and less liable to repeat the offense which removed him from society. A well regulated physique is the first step toward reformation. This is a single phase of the institutional policy of the present administration governing Michigan. We are firmly convinced that the product of state institutions should be—not commercial articles destined to swell the state treasury—but, men and women.

#### Health Insurance in Czecho-Slovakia

The *Riforma Medica* of Naples states that the government of Czecho-Slovakia has organized a system of insurance against disease, obligatory for all with incomes less than 20,000 crowns and optional above this. The choice of the physician is unrestricted.

#### Baby Health Survey in District of Columbia

Underwood & Underwood, N. Y. Every child up to six years old in the District of Columbia is being examined by the Child Welfare Society with the view of compiling statistics as to their general health and to make them fit for school.

# Occupational Therapy in American Institutions\*

## Therapy, No Longer Limited to Nostrums, Becomes Concerned with Problems of Living

BY ADOLF MEYER, PROFESSOR OF PSYCHIATRY, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

THERE was a time when physicians and the public thought the art of medicine consisted mainly in diagnosing more or less mysterious diseases and "prescribing" for them. Each disease was supposed to have its program of treatment, and to this day the patient and the family expect a set of medicines and a diet, and a change of climate if necessary, or at least a rest-cure so as to fight and conquer "the disease." No branch of medicine has learned as clearly as psychiatry that after all many of these formidable diseases are largely problems of adaptation and not some mysterious devil in disguise to be exorcised by asafetida and other usually bitter and possibly alcoholic stuffs; and psychiatry has been among the first to recognize the need of adaptation and the value of work as a sovereign help in the problems of adaptation.

It so happened that in the first medical paper I ever presented, about December, 1892, or January, 1893,—curiously enough before the Chicago Pathological Society, where one would least expect discussions of occupation—I asked my new neighbors and colleagues for suggestions as to the tastes and best lines of occupation for American patients. The proper use of time in some helpful and gratifying activity appeared to me a fundamental issue in the treatment of any neuropsychiatric patient. In May, 1893, I went to Kankakee and found in that institution some ward work and shop work. Later, under the inspiration of Isabel Davenport, some gardening was introduced for the women in her convalescent cottages, but I also found there a little of a feeling which prejudiced quite conspicuously much of the contemporary attitude toward this question.

Among a most interesting collection of abstracts from the history of American institutions put at my disposal by Dr. William R. Dunton, I find a report on the employment of the insane by a committee from the Michigan institutions, dated 1882 and

*Mind is energy. Its measured control toward socially useful ends is the social criterion of intelligence. Mental problems are problems of living. Failures of adjustment, even in the mentally incompetent find a corrective in carefully planned activities.*

*Whether the patient is a misfit from a personality disorder or a physical handicap, occupational therapy tends to create interest, correlated activity, organization, which in their perfect balance spell physical and mental health. Not physical restoration only, but readjustment must be considered the ultimate health objective.*

signed by Dr. Henry M. Hurd. The Committee had visited European institutions and had been especially impressed by their use of occupation as a substitute for restraint, but they expressed the fear that the presence of private patients would interfere with the introduction of occupation. The conclusions contain the following statements:

Employment of some sort should be made obligatory for all able-bodied patients. . . . (But) it would be feared that such measures would meet with much opposition from all quarters. . . . It might, consequently, be best to arrange at first for the employment of state patients and to procure legislative sanction of the step. If this works advantageously it will be comparatively easy to extend the system to other patients.

This represents the attitude of many hospital men of the time. Industrial shops and work in laundry and kitchen and on the wards were the achievements of that program—very largely planned to relieve the employees.

### The Newer Concept

A new step was to arise from a freer conception of work, from a concept of free and pleasant and profitable occupation—including recreation and any form of healthful enjoyment as the leading principle.

When in 1895 I was transplanted

to Worcester, Mass., there was little in the atmosphere to foster interest in occupation. Ward work and a few shops were managed merely from the point of view of utility. Only the McLean Hospital had the beginnings of some organized recreative occupations. From 1902 it was my good fortune to have to work on Ward's Island in a division which then was under the immediate direction of an unusually active and enterprising man, Dr. Emmett C. Dent, always eager for therapeutic results and untiring in his development of hospital principles in the face of very cramped opportunities. In this new atmosphere I was greatly assisted by the wholesome human understanding of my helpmate, Mrs. Meyer, who under these conditions may have been one of the first, if not the first, to introduce a new systematized type of activity into the wards of a state institution.

She had become a great help to my patients in visiting them in my ward and had instituted visits to the homes. She was probably the first social worker with a systematic program of help to patient, family, and physician, just before Miss Louise Schuyler urged the introduction of a very eleemosynary type of aftercare in November, 1906. When in 1907 a social worker, Miss Horton, was appointed, Mrs. Meyer turned her attention to the occupation and organized recreation of the patients on the ward, not only in the shops and amusement hall, but in the employment of the available time on the ward.

Shortly after that, in 1909, Miss Lathrop and the Chicago School of Civics and Philanthropy undertook a course of training in play and occupation for nurses, and Miss Wright was chosen to receive this training, and she returned to organize the work throughout the institution—with a wise balance between organized shopwork and more individual work on the wards.

It had long been interesting to see how groups of a few excited patients can be seated in a corner in a small circle of two or three settees and kept contented picking the hair of mattresses, or doing simple tasks not

\*Read before the Annual Meeting of the American Occupational Therapy Association, Baltimore, Md., September, 1920. Published through the courtesy of the Archives of Occupational Therapy.

too readily arousing the desire for big movements and uncontrollable excitement and yet not too taxing to their patience. Groups of patients with raffia and basket work, or with various kinds of handwork and weaving and bookbinding and metal and leather work, took the place of the bored wall flowers and of troublesome mischief-makers. A pleasure in achievement, a real pleasure in the use and capacity of one's hands and muscles, and a happy appreciation of time were thereafter used as incentives in the management of our patients, instead of relying upon abstract exhortations to cheer up and to behave according to abstract or repressive rules. The main advance of the new scheme was the blending of work and pleasure and a wise individualization in occupational methods.

When the Phipps Clinic was opened, we were able to secure the services of Mrs. Slagle, who, with her successors—Mrs. Price and Miss DeHoff, and Mr. Marion, Mr. Russell, and Mr. Case—brought us to the level now represented at the Phipps Clinic.

Somehow the evolution of occupational therapy represents to me a very important manifestation of a general broadening of human philosophy. This development of the valuation of time and work is not accidental, but is to be regarded as a part of the great espousal of the value of reality and actuality rather than of mere thinking and reasoning and fancy, as characteristic of the Nineteenth Century and the present day.

### The Personal Problem

The culminating feature of evolution is man's capacity of imagination and the use of time with foresight based on a corresponding appreciation of the past and of the present. We know more definitely than ever that the twenty-four hours of the day are the problem of nursing and immediate therapy, and not the medicines taken *t.i.d.* Something apparently self-evident has taken its proper position in our attention. Just as in its medical aspects we have come to value an appreciation of the exceedingly simple facts of basal metabolism and to measure the expenditure of energy by the amount of CO<sub>2</sub> produced, so the simple fact of a patient's employment of time has become an important index to the physician and nurse. The most important factor in this progress is the newer conception of mental problems as problems of living, and not merely as diseases of a structural and toxic

nature on the one hand or of a final lasting constitutional disorder on the other. The formulation in terms of habit deterioration of even those grave mental disorders presenting the serious problem of terminal dementia made systematic engagement of interest and concern about the actual use of time and work an obligation and necessity.

It is very interesting that the progress of all the fundamental sciences has shown the same trend during the last thirty years. The nineties of the Nineteenth and the first decade of the Twentieth Century marked the rise of energetics,—so effectively brought home to all scientists by Professor Ostwald in his lectures in this country some fifteen years ago—a determination to replace the interest in inert matter by a broad conception of the world of physics and chemistry in terms of energies, which means literally "applications of work." Similarly, during this same period the study of human and of animal life gave birth to the concept of behaviorism with its emphasis on performance as the fundamental formulation of what had figured up to that time on the throne of an abstract timeless psychology, curiously enough, first invaded by science in the form of studies in reaction-time. Direct experience and performance were everywhere acknowledged as the fullest type of life. Thought, reason and fancy were more and more recognized as merely a step to action, and mental life in general as the integrator of time, giving us the fullest sense of past, present and future, but, after all, the best type of reality and actuality only in real performance. We all know how fancy and abstract thought can go far afield—undisciplined, uncensored, uncorrected; while performance is its own judge and regulator and therefore the most dependable and influential part of life. Our body is not merely so many pounds of flesh and bone figuring as a machine, with an abstract mind or soul added to it. It is throughout a live organism pulsating with its rhythm of rest and activity, beating time (as we might say) in ever so many ways, most readily intelligible and in the full bloom of its nature when it feels itself as one of those great self-guiding energy-transformers which constitute the real world of living beings. Our conception of man is that of an organism that maintains and balances itself in the world of reality and actuality by being in active life and active use, i.e., using and living and acting its

time in harmony with its own nature and the nature about it. It is the use that we make of ourselves that gives the ultimate stamp to our every organ.

### Rhythmic Sequences

This growing conviction that personality is fundamentally determined by performance rather than by mere good-will and good intention rapidly became the backbone of our psychology and psychopathology. It became a fair task for our ingenuity to obtain performance wherever it had failed to come spontaneously and thereby to serve the organism in the task of keeping itself in good form.

This philosophy of reality, of work and time, seen in all the sciences appeals to me because it expresses, with respect for fact, the simple and yet most valuable experiences of real life.

The whole of human organization has its shape in a kind of rhythm. It is not enough that our hearts should beat in a useful rhythm, always kept up to a standard at which it can meet rest as well as wholesome strain without upset. There are many other rhythms which we must be attuned to: the larger rhythms of night and day, of sleep and waking hours, of hunger and its gratification, and finally the big four—work and play and rest and sleep, which our organism must be able to balance even under difficulty. The only way to attain balance in all this is actual doing, actual practice, a program of wholesome living as the basis of wholesome feeling and thinking and fancy and interests.

Thus, with our patients, we naturally begin with a natural simple régime of pleasurable ease, the creation of an orderly rhythm in the atmosphere (a wise rule of using all our natural rhythms), the sense of a day simply and naturally spent, perhaps with some music and restful dance and play, and with some glimpses of activities which any one can hope to achieve and derive satisfaction from.

In this frame of rhythm and order of time, we naturally heed also the other factors—the personal interests and personal fitness. A large proportion of our patients present inferiority feelings, often over a sense of awkwardness and inability to use the hands to produce things worth while, i.e., respected by themselves or others. To get the pleasure and pride of achievement and use of one's hands and muscles, the feeling of worthwhileness of a little effort and of a well fitted use of time is the basic

remedy for the blasé tedium that characterizes the indifference or the hopeless depression which so often stands in the way of rallying thwarted personalities. I am convinced that a premium should be put on the production of things that are finished in one or a few sittings and yet have an independent emotional value. They must give the satisfaction of completion and achievement, and that in the eye of the maker and of those for whom he has tried to work. Performance and completion form also the backbone and essence of what Pierre Janet has so well described as the "fonction du réel"—the realization of reality, bringing the very soul of man out of dreams of eternity to the full sense and appreciation of actuality.

Our rôle consists in giving opportunities rather than prescriptions. There must be opportunities to work, opportunities to do and to plan and create, and to learn to use material. There are bound to be valuable opportunities for timely and actually deserved approval and encouragement. It is not a question of specific prescriptions, but of opportunities, ex-

cept perhaps where suggestions can be derived from the history of the patient and a minute study of the trends of fancy and even delusions reveals the lines of predilections and native longings—yet even here the physician would only exert his ingenuity to adapt opportunities.

I see in all this a profound importance extending far beyond our special field. Our efforts seem to me destined to be the soil for helps of much wider applicability. Present day humanity seems to suffer from a deluded craze for finding substitutes for actual work. It seems more difficult than ever to guide with the traditional preachments.

Our industrialism has created the false, because one-sided, idea of success in production to the point of overproduction, bringing with it a kind of nausea to the worker and a delirium of the trader living on advertisement and salesmanship, instead of sound economics of a fair and sane distribution of the goods of this world, according to need and an education of the public as to where and how to find the best and worthiest.

The man of today has lost the capacity and pride of workmanship and has substituted for it a measure in terms of money; and now his money proves to be of uncertain value. A great deal of activity, to be individually and socially acceptable and exciting enough and mentionable for social exhibition of one's worth, has to be of the nature of conspicuous waste, a class performance like athletics and golf and racing about the country, and a display of rapidly changing fashions. Work and play, ambition and satisfaction, are apt to lose their necessary contact with the natural rhythms of appetite and gratification, vision and performance, and rhythmically recurrent cycles possible of completion—of work and play and rest and sleep.

This special work, which tries to do justice to special human needs is destined to serve again as the nucleus of a great gain for the normal as well. It will work like the Montessori system of education. Grown out of the needs of defective children, it has become the source of inspiration and methods for a freer education of all children.

## Physical Education in Oklahoma City Schools

By J. A. WHITEFORD, SUPERINTENDENT OF SCHOOLS, OKLAHOMA CITY, OKLA.\*

PHYSICAL work in the Oklahoma City public schools may be divided, according to the division of the school system, into elementary, intermediate, and high schools. There are in the school system thirty elementary schools, with approximately sixteen thousand students enrolled; three junior high or intermediate schools, with an enrollment of about 2,650; and a senior high school which enrolls something over two thousand five hundred students. Physical education of the students of the thirty-five schools of the city is in charge of a physical staff consisting of a director, four men and five women assistants giving full time to physical work, and four men and about ten women devoting part time to physical instruction.

### Physical Education Compulsory

The elementary schools include students from the first to the sixth grade. For these grades, the first type of physical work is free play, before and after school. Play is

supervised at morning and afternoon recesses, consisting for the first three grades of singing and folk games; of group games for the next two grades; and of competitive games for the two

upper grades. Leagues are organized within the school for competitive games for the sixth and seventh grades, and occasional games are arranged with other schools, in addi-

The gymnasiums are equipped for complete and systematic physical work. Each student is required to have three hours of physical work each week. The indoor training is supplemented with group games and mass athletics in the open.

\*The illustrations for this article were supplied by Layton, Smith and Forsyth, architects.

One hour a week is required to be devoted to swimming, graded in beginning, advanced, and life-saving classes.

tion. A "washout" period, three minutes in length, in which all windows in the room are thrown wide open, and vigorous setting up exercises given, is scheduled three times a day in every elementary school room in the system. Finally, a system of efficiency tests is provided for the fourth, fifth, sixth, and seventh grades, alternate weeks being devoted to practice and tests in such forms of physical work as running, jumping, chinning, etc. All work of this nature is compulsory for all students in these grades.

In the intermediate grades, that is—in the three junior high schools of the city, is found the most complete and systematic physical work of the system. The junior high schools are splendidly equipped with gymnasiums, swimming pools and large athletic fields, two schools having fields covering a full-size city block, and the third two such blocks. Each student of junior high rank is required to have three hours of physical work each week; one hour devoted to formal gymnastics, including setting-up exercises, marching, posture work, apparatus work, and dances; one hour to swimming, graded in beginning, advanced, and life-saving classes; and one hour of out-of-door work, along the line of group games and mass athletics.

In addition to the compulsory work outlined above, an optional program of athletic competition is possible. For boys, contests are held in football, basketball, track, baseball, cross-country, soccer, tennis, and swimming; for girls, in volley-ball, basketball, playground ball, dodgeball, track

field hockey, tennis and swimming. Games are scheduled and contests held between classes or teams within the schools, and leagues are arranged providing for series of contests in popular sports for both boys and girls between the three junior high schools. During the football season just closed, six teams contested in league games, each team playing six games; and over one hundred boys received elementary football instruction.

### Some Courses Elective

In the Central High School, physical work is elective throughout. Work may be divided into regular advanced gymnasium work, and athletics. Regular gymnasium work for

boys includes one day each week devoted to apparatus work, one to posture work, one to indoor track, another to hygiene instruction, and one to competitive games, each member of the class being included in a team which plays a schedule of games in a regular league arrangement. A similar arrangement is used for girls, group dancing being substituted for indoor track and apparatus work. Practically all students enrolled in gymnasium classes are sophomores.

The second phase of physical work in the Senior High School is along the line of athletics. Interclass athletics are conducted in football, basketball, track, cross-country baseball, swimming and tennis for boys; and in basketball, volley-ball, tennis and swimming for girls. No interscholastic athletic contests are arranged in which girls participate; but interscholastic contests for boys are scheduled in football, basketball, track baseball, and tennis. The Central High School is a member of the Oklahoma High School Athletic Association, and of the Oklahoma Central Conference.

It might be mentioned here that a unified system of coaching is used in the senior and junior high schools, so that the junior schools serve as "feeders" to the senior high school, sending to this school several hundred students each year who are trained in the fundamentals of the coaching system in use in the senior high school.

Another point of interest is the financing of athletics in the junior and senior high schools. Athletic expenses in the junior high schools, in-

A view of the cafeteria in the Junior High School, Oklahoma City, a department well supervised, which it is considered is a highly important part of the program of physical betterment.

cluding cost of equipment and the like, are provided by annual appropriations of the Board of Education, and all contests in the senior high school are financed by an Athletic Association composed of the students of the high school, which pays all ex-

penses save the salary of coaches, which is provided by the Board of Education.

Plans are being worked out by which the three junior high schools, with their splendid athletic fields, swimming pools, and gymnasiums, are

to be used as community centers, so that the public may have the use of the athletic equipment of the school system as far as possible. Competent supervisors will be placed in charge and the schools ready for use as community centers the year around.

# The East Harlem Health Center in Action

By HELEN C. DENMAN, THE AMERICAN RED CROSS, NEW YORK CITY

WITH the formal opening in November of the East Harlem Health Center in New York City was launched a community experiment of unusual significance. Not only does the new center unite all the health agencies in the district but it brings together for cooperative effort the welfare agencies as well. Twenty-one organizations, ten of them engaged in community and family welfare work and the others devoted to health and nursing, have come together in the new enterprise. It can safely be said that this is the first undertaking of the kind in the country where the principle of coordination has been applied consistently and on such a large scale in such a fertile field for endeavor as New York's upper East Side.

The area selected for the work of the new health center covers eighty-three city blocks and is a census unit of approximately one hundred thousand souls. It runs, roughly speaking, from the East River to Third Avenue and includes within these limits what is known as Little Italy, a large Jewish population, and a small Irish colony. Housing conditions are almost, if not quite, the worst in any section of the city; the buildings date back twenty-five years, are dependent

upon gas light, and have none but the barest sanitary conveniences. Needless to say, the diseases which thrive on lack of sunlight and air find the district a happy hunting ground.

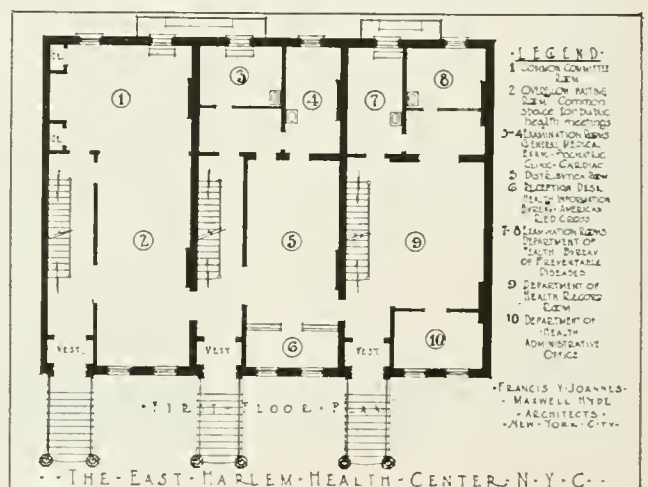

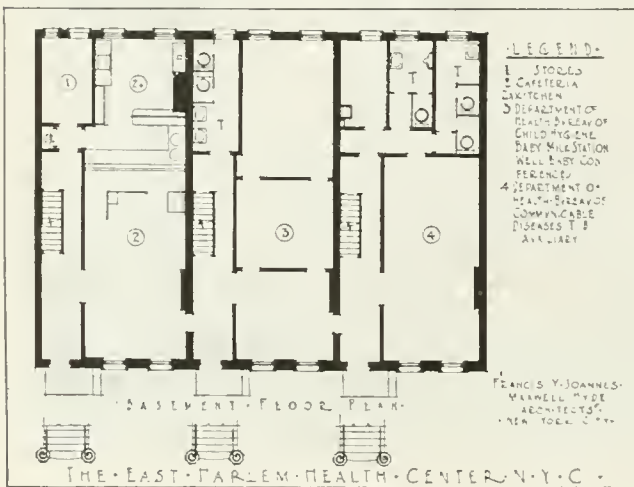

In the geographical center of this area the new Health Center has taken up its quarters in three buildings formerly occupied by a hospital. Here may be found the local district work of the New York City Department of Health with its Bureaus of Child Hygiene and Preventable Diseases; the Association for the Aid of Crippled Children; the Association for the Prevention and Relief of Heart Disease; the New York Tuberculosis Association; the American Social Hygiene Association; the Occupation Therapy Society of New York; the Committee on Dispensary Development; the York County Chapter Red Cross; and the nursing agencies which form the nucleus of any health center, the New York Maternity Center Association; the Henry Street Settlement, and the New York Babies Dairy. Side by side with these are the welfare agencies such as the New York State Charities Aid Association; the Charity Organization Society; the United Hebrew Charities; and the New York City Association for Improving the Condition of the

Poor. The only agencies not to occupy office or clinical space are five neighborhood houses which from the very nature of their work can serve the district better from scattered vantage points than from a central base. They are, however, keeping in close touch with the group.

## A Time Saving Device

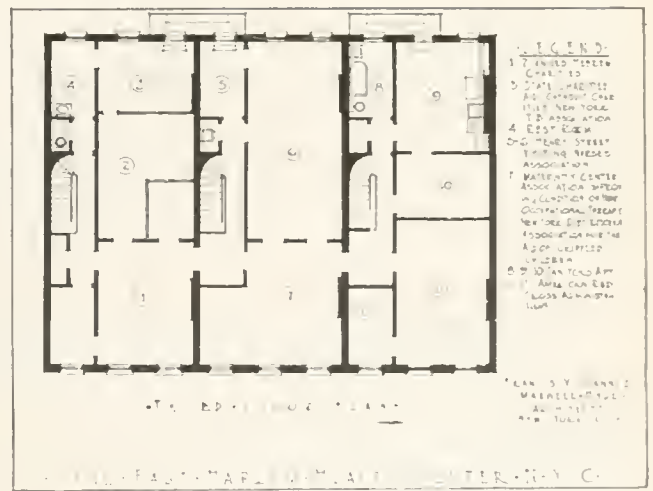

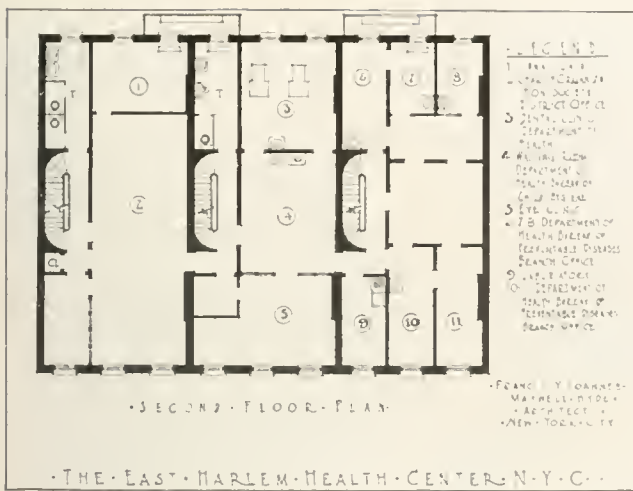

The close connection of poverty with disease is one with which every physician and social worker is familiar, and the practical value of this coordination of health work and family welfare activity is so obvious that one wonders why it is not more universally applied. In having easy access to the case files of the various agencies, each organization is spared the duplication of effort which so often occurs, and time and energy are saved which can be poured back into East Harlem. In the same fashion, by bringing together clinics and offices into one operating unit, a case which is one for the family welfare agencies to handle equally with the health or nursing agencies can be quickly and effectively passed from one to the other.

Not only is the new Health Center unique from the point of view of coordination, but it has another claim to

Three buildings, formerly occupied by a hospital were remodeled to house the East Harlem Health Center.

The physical plant is developed to facilitate the cooperative activities of the several agencies taking part in the scheme.

The departments provided for are an earnest of the completeness of the cooperative service.

The permanent value of such an enterprise proves itself through the economy of effort in the labor over common problems.

distinction in the comprehensiveness of its program. Part of its policy is to discover any health needs in East Harlem which are not being met by the agencies already in the field, and to introduce the agencies which will meet the demand. To accomplish this purpose, the Health Center is developing a system of "health bookkeeping." In conjunction with the City Department of Health, the New York County Chapter Red Cross Health Service is studying the vital statistics of the district from 1915 to 1920. The infant mortality rate during that period has been computed. The causes of death with the degree of prevalence of the various diseases have also been determined. Not only will this statistical service demonstrate any shortcomings in the program of the Health Center, but it is expected to provide the Center with a careful accounting of the liabilities and assets with which it is starting its work for the better health of the community. With this material in hand at the beginning, the Center will be better able to show what it has accomplished at the end of any given time.

Already the Health Center has been responsible for a number of important movements toward better health extending beyond the confines of East Harlem. Seventeen thousand children in the district have been given the Schick Test through the agency of the New York County Chapter of the Red Cross and the City Department of Health. About one-third were found to be susceptible to diphtheria and were given the toxin for immunization. As a result of this cooperation between the New York County Chapter of the American Red Cross, and the New York City Health Department, the death rate among chil-

dren from diphtheria has been reduced 20 per cent, the official figures of the Health Department showing that the deaths from diphtheria for 1921 are 20 per cent lower than for 1920. The Health Service of the American Red Cross provided the money at the request of the Health Commissioner to make a demonstration of the Schick Test in forty-four public schools during 1921. The demonstration lasted three months, the Health Department providing the personnel and the local Chapter of the American Red Cross providing the funds. In this demonstration over 52,000 school children were tested, about twenty thousand of whom were found to be susceptible to diphtheria and were then given the toxin antitoxin to make them immune. As in every case the consent of the parents had to be obtained before the test was made, this meant a forward step in public education for the prevention of sickness.

One of the best results of this demonstration has been the recent vote of the Board of Estimate appropriating funds for the Health Department to continue the Schick Test work in the New York City schools. Finally, as a direct result of the diphtheria immunization work in New York City this service is now underway in a number of places throughout the Atlantic Division including Schenectady, Syracuse and Buffalo. In all these places the American Red Cross is cooperating in the movement.

### Popular Health Education

In the East Harlem Health Center district 716 children of pre-school age were also prepared for school in September through an interesting experiment in health

supervision. Physicians from the City Health Department examined them for physical defects; through the cooperation of psychologists from Teachers' College they were mentally tested and graded; and the Red Cross provided a nurse to follow up on the physical examinations and see that physical defects were remedied. The Red Cross Health Service also provided a dental hygiene clinic for those children during the summer.

Public health education, teaching all classes in East Harlem how to get well and stay well, is to be as much a part of the work of the new Center as relief for the sick and indigent. A plan for promoting interest in health measures through extensive local publicity has been outlined by the twenty-one agencies. It is the purpose of the several agencies to cooperate to the fullest extent in health educational measures directed definitely toward the needs of the groups served. Literature, lectures, social work and clinics will combine to spread the gospel of health and to give an objective demonstration of health gains through health practice. Out of such an experiment may be expected to develop the ability to cope with the constant menace of disease.

The New York County Chapter of the Red Cross which took the first steps in initiating the center, has agreed to finance it for three years as a demonstration. Its existence after 1924 will depend entirely upon whether it has proved its essential value to the community. Officers of the center, as at present constituted, are: Honorary president, Dr. Royal S. Copeland, City Health Commissioner; chairman, Dr. James Alexander Miller; secretary and executive officer, Kenneth Widdemer. The exe-

cutive committee includes the following representative numbers: Homer Folks, New York State Charities Aid Association, chairman; Dr. L. I. Harris, and C. L. Kohler, of the City Department of Health; Dr. James Alexander Miller and Dr. Wm. F. Snow, from the Health Service Committee of the Red Cross; Miss Annie

Goodrich, of the Henry Street Settlement, Miss Anne Stevens, of the Maternity Center Association; Lawson Purdy and Bailey B. Burritt, representing family welfare work; Gaylord White, representing settlements and local welfare work; and Father Thomas Kane and Dr. A. M. D. Riggio, representing East Harlem.

sweeping is prohibited while the children occupy the building.

Adequate ventilation, lighting and heating should be provided. All windows and doors of the nursery should be equipped with screens. Wire screens should be placed around all stoves, open fire-places or other heating apparatus in the nursery department.

The use of common washcloths, towels, combs, hair brushes, and drinking cups is prohibited. Arrangement should be made for the sterilizing of washcloths, bottles and nipples daily and for sending out laundry (towels, crib sheets and blankets).

All bottles and nipples shall be provided by the nursery. No bottle or nipple shall be used a second time during the day unless it has been thoroughly scrubbed placed in water and thereafter thoroughly washed and boiled. No diapers in an unclean condition shall be removed from the premises.

Unless the clothing on a child is thoroughly clean on admission, a suitable garment, the property of the nursery, shall be worn through the day and every such garment shall be marked for identification unless a clean garment is provided daily.

IV. MEDICAL CARE.—A thorough medical examination of each new child admitted to the nursery shall be made and a health certificate signed by a physician designated by the nursery shall be required. The child should be stripped and a record kept of all examinations.

Provisions shall be made for medical supervision of children either by cooperation with clinics or by the employment of a visiting physician. The physician shall make regular visits to the nursery and shall re-examine every regularly attending child at least once a month.

An isolation room for cases of suspected contagious diseases shall be provided.

The nurse shall carefully observe each child every morning at the time of admission and if signs of contagious disease are noted, the child must be placed in the isolation room and kept entirely apart from the other children and a physician or the department of health notified at once. She should supervise the treatment of minor ailments.

V. DIET.—The physician should prescribe formulas and diet. Bottle babies should receive their feedings on regular schedule.

All older children in care should receive a warm and nourishing noon

## California Day Nurseries

IN a community program for child welfare the day nursery may have a place. Just what this place may be is a question which every nursery should consider carefully. Experience proves that no social agency has been more abused.

No one will question that the ideal of family life for children, particularly for young children, is the mother in the home supervising their care. When this arrangement is threatened by inadequate income, illness, or industrial conditions, the most vital consideration is the stability of the family group. All community resources should be enlisted to preserve it. But after all other resources fail there may yet remain cases of children requiring day nursery care. The nursery should always inquire carefully into the case of every child seeking admittance to determine whether there may not be other solution for the family problem.

In the day nursery the health problem is paramount. The average day nursery child comes from a home in which various causes contribute to a reduced standard of sanitation and hygiene. Also the age of the children involved makes them more susceptible to contagious and infectious troubles. The larger the group, the greater the danger.

Considering this menace to health the following standards for the conduct of day nurseries have been adopted in California.

### Day Nursery Standards

1. YARD.—Ample play space should be provided. The surface of the play yard should be made dust-free by the use of sand, gravel or tanbark. Stone and asphalt do not make good play surfaces. A portion of the yard should be shaded. If there are no trees, shade or awnings should be provided. There should be a drinking fountain in the yard. The yard should be provided with play apparatus.

II. BUILDINGS.—(1) *Kindergar-*

*ten or playroom.*—This should be the largest room in the building. It should contain tables, chairs, and a safe heating apparatus. Suitable toys, of educational value, such as blocks, bean bags, balls, and dolls should be provided. Sewing, knitting and weaving materials for the "play-work" should be provided for children of kindergarten age.

(2) *Nursery or sleeping-room for children under two.*—This room should be provided with dark shades for windows; metal cribs with woven wire springs, two feet apart on all sides; heavy folded blankets serving as mattresses; good quality of rubber sheeting; crib sheets; cotton crib blankets.

(3) *Diet Kitchen.*—A small room containing a cupboard for lunches, icebox for babies' milk, small work table, a gas plate or small oil burner. A sink is indispensable.

(4) *Toilets.*—One toilet to every twenty children should be furnished. There should be separate toilets for boys and girls beyond nursery age. Toilet paper should be furnished.

It is suggested that a stationary wooden foot bench be fixed before the toilets and that a patent wooden seat for little children be provided.

(5) *Lavatories.*—One lavatory bowl to every ten children should be provided. There should be furnished also an adequate supply of the following: Soap, individual towels or paper toweling, wash cloths or cut gauze, and drinking fountains.

Every nursery building shall be equipped with adequate fire protection which meets the requirements of the local fire ordinances. It is recommended that a chemical fire extinguisher be placed on every floor. They should be renewed at least once a year.

III. HYGIENE AND SANITATION.—All rules of hygiene and sanitation of the local health department should be rigidly observed. Walls, ceiling and floors should be, as far as possible, washable. Dry dusting or

meal. In addition to the noon meal it is recommended that a mid-morning and mid-afternoon lunch of bread, butter, and milk be provided.

Nursing mothers should be urged and encouraged to nurse their babies as long as the children gain.

Nursing mothers should be urged to go into the nursery at appointed times to nurse the baby. A hot drink and a low chair would be a helpful provision.

VI. SUPERVISION.—The nursery should be under the supervision of a trained nurse who shall be responsible for the sanitation, hygiene, preparation of formulas and health care of the nursery.

The woman directly in charge of the children should understand the proper care of children and should be able intelligently to direct their activities.

A regular schedule for meals, naps, nursing of infants, and bottle feeding should be maintained.

Emphasis should be laid on the teaching of personal hygiene to the children.

There shall be employed by the day nursery a sufficient number of workers to insure adequate supervision and care of children at all times.

A complete segregation should be maintained between infants, run-arounds, and older children.

VII. ADMISSIONS.—The State Board of Charities and Corrections deprecate the day nursery care of nursing babies. If, however, their care seems absolutely necessary, no babies under three months of age should be received. Preferably none under one year.

Homes of children admitted to the nurseries should be inspected before a child is accepted. In emergency cases the home shall be visited not later than one week after the child has entered. Any doubtful or dangerous conditions found in homes must be reported to the proper officers of the nursery and to the Board of Health.

VIII. RECORDS, SOCIAL AND MEDICAL.—Records should be kept. The social data should include the following recommendations:

- (1) Child's name.
- (2) Child's age.
- (3) When admitted.
- (4) Serious illness.
- (5) Names of both parents.
- (6) Parents' address.
- (7) Occupation of each parent.
- (8) Nationality.
- (9) Earnings of each parent.
- (10) Entire earnings of family.
- (11) Religion of each parent.
- (12) Mother's reason for working.

(13) Whether widow, married, deserted, or separated.

(14) Number of children in family.

(15) Number at work or in school.

A record of the medical examination of each child should be kept.

It is urged by the State Board of Charities and Corrections that all day

nurseries become affiliated with the National Federation of Day Nurseries, office 105 East 22nd street, New York City. They publish at a nominal cost a set of record forms which cover the records required by this Board; also a dietary and pamphlets helpful to the manager, nurse and matron.

## Dental Clinics in Hospitals

BY MICHAEL M. DAVIS, JR., PH.D., CHIEF, SERVICE BUREAU ON DISPENSARIES, AMERICAN HOSPITAL ASSOCIATION, NEW YORK CITY

AT THE request of Mr. Julius Rosenwald of Chicago, the Service Bureau on Dispensary and Community Relations of Hospitals of the American Hospital Association has prepared a report on dental needs and dental facilities in a number of selected cities and medical institutions throughout the country. Four types of dental clinics have been developed in the United States: (1) those in connection with industrial or commercial establishments; (2) those in connection with hospitals and dispensaries; (3) those in public schools; (4) public health clinics in public schools, independent local clinics, or as part of a community dental program.

In order to obtain information as to the number of hospitals and dispensaries offering dental service, questionnaires were sent to 282 general hospitals, including almost all those in the United States having a capacity of one hundred beds or over. Fifty-one per cent answered the inquiries. Eighty-nine of the 144 replies reported dental services in the hospital; in four, a dental service was in the process of establishment; in twelve, it was being planned, and in two, it was hoped for. The answers showed that dental service was either definitely established or well under way in more than one-third of the 282 larger general hospitals of the United States.

In 46 of these hospitals, dental service is recognized as of departmental rank, with assigned beds in some instances and in others with use of beds as needed. In 32 of the 89, dental service is not recognized as a department, but is organized for purposes of consultation and diagnosis. In 11 of the 89 hospitals, dental work includes offering dental treatment to patients but is not recognized as a general department of the hospital.

Of the 89 hospitals with dental service, 41 maintained dental work

for their ward patients, but had no general dental clinic. Seventeen of the 89 hospitals had no dispensary clinics of any kind, but of the remaining 72 which had some out-patient department, 48 had a dental clinic as part thereof.

Most of these clinics were for dental treatment as well as for diagnosis, only five being limited to diagnosis only.

The great pressure for dental service is illustrated by the fact that a large number of these hospitals have found it necessary to limit their dental clinic for the use of patients referred from other parts of the hospital or dispensary.

Superintendents from all the leading hospitals recognized the desirability of dental service. The question was rather one of organization and expense in carrying on the work.

Recommendations of the committee in regard to dental service in hospitals were:

- (1) A dentist competent as a dental diagnostician should be recognized with adequate rank on the staff of the hospital, and should be given the necessary facilities, such as access to the x-ray and to beds when necessary.
- (2) The primary responsibility of the hospital in dental care is the dental diagnosis of patients whose mouth conditions are involved as a factor in the disease for which the hospital accepted these cases, and for whom dental treatment is necessary in order that the hospital's medical or surgical work shall attain satisfactory results. In other words, a hospital cannot carry out adequate diagnosis and treatment without undertaking dental diagnosis, and in some instances dental treatment also.
- (3) A routine dental examination of hospital cases should be included as part of the physical examination.
- (4) Hospitals maintaining out-patient departments should include a dental clinic for treatment purposes as part of this out-patient department, unless

by some definite affiliation with another accessible dental clinic, the necessary dental care of its patients can be assured. (5) The service of a dental clinic as part of the hospital out-patient department must ordinarily be limited in order to avoid overcrowding. Patients should be accepted in the following order:

The cases would naturally be limited to those already received by the hospital whose mouth conditions are involved in a general medical or surgical condition or those patients who have been referred to the dental clinic from other medical or community agencies with the indication that

the dental conditions are involved in the general condition of the patient. Other cases would include emergency work for the relief of pain.

The dental organization thought to be most efficient by the committee should consist of a dentist recognized as head of the dental service of the hospital, assistant dentists, dental interns, and a dental hygienist. The head dentist should be in charge of the organization of the dental work, including the out-patient clinic; assistant dentists should act as visiting members of the staff; while dental interns could assist in the therapeutic work of the out-patient department

and also be given advanced dental education in both curative and diagnostic work. The dental hygienist would be a desirable member of the staff and could serve as an agent for cleaning the teeth of bed patients.

Fees covering cost of treatment should be charged but remitted if the patients are unable to pay.

Such dental clinics could give free prophylactic work to children of school age. The cost of this service is less than five per cent of the usual per capita cost of school education. For dental care other than prophylaxis a charge should be made, these fees being remitted when necessary.

## Our Dangerous School Houses

ALMOST six million dollars represents the fire loss in schools from preventable causes during 1919 according to an estimate published in *The American City*. The heaviest damage, \$556,427, was caused from defective chimneys and flues in 1919, whereas in 1918 stoves, furnaces, boilers, and boiler pipes held first place. Other preventable school building fires were caused by open lights, sparks on roof, matches and smoking, while petroleum and its products, gas, hot ashes, coals, and open fires caused lesser losses.

The report by the Meyer Legislative Committee which surveyed the fire danger in New York City schools discovered that of 695 schools in the five boroughs, 496 had violated fire department regulations. A survey of other cities reveals like discrepancies and only sixty-five cities were found in the United States which had provided every school building within its limits with fire alarm boxes.

The cities who qualify for the safety honor roll are Alameda, Calif.; Tulare, Calif.; Naugatuck, Conn.; Winsted, Conn.; Jacksonville, Fla.; Augusta, Ga.; Nampa, Idaho; Oak Park, Ill.; Hammond, Ind.; Clinton, Iowa; Rumford, Me.; Belmont, Mass.; Beverly, Mass.; Boston, Mass.; Cohasset, Mass.; Everett, Mass.; Fall River, Mass.; Holyoke, Mass.; Marblehead, Mass.; Newton, Mass.; Quincy, Mass.; Reading, Mass.; Salem, Mass.; Sharon, Mass.; Swampscott, Mass.; Walpole, Mass.; Harbor Beach, Mich.; Cloquet, Minn.; Anaconda, Mont.; Goldfield, Nev.; East Orange, N. J.; Nutley, N. J.; Passaic, N. J.; Union, N. J.; Union Hill, N. J.; Buffalo, N. Y.; Cortland, N. Y.; Flushing, N. Y.; Harrison, N. Y.; Ithaca, N. Y.; Malone, N. Y.;

Niagara Falls, N. Y.; New York, N. Y.; Rochester, N. Y.; Syracuse, N. Y.; Utica, N. Y.; Walden, N. Y.; Watertown, N. Y.; Conneaut, Ohio; Warren, Ohio; LaGrande, Ore.; Pendleton, Ore.; Forty-Fort, Pa.; Beaver Falls, Pa.; McKeesport, Pa.; West Newton, Pa.; Woonsocket, R. I.; Columbia, S. C.; Salt Lake City, Utah; Norfolk, Va.; Spokane, Wash.; Ashland, Wis.; Manitowoc, Wis.; Milwaukee, Wis.; Superior, Wis.

According to statistics compiled by the National Board of Fire Underwriters through its actuarial bureau, there are on the average five school fires a day. Recorded school house losses in the United States during the four-year period 1916 to 1919, inclusive, amounted to \$19,846,038. This would reach probably \$25,000,000 if

unreported and uninsured fires were taken into account.

The great loss of life in the large school fires such as those in Collingwood, Ohio, Peabody, Mass., and in the Hochagela School in Montreal is largely due to panic and not primarily to fire itself. An organized fire department easily reached is considered the only effective means of handling panic and preventing extensive loss of life. For this reason, the installation of fire alarm boxes in every school house in the United States is urged to safeguard the children.—Rollin Kirby in the *New York World*. Courtesy National Board of Fire Underwriters.

In view of the many school house fires, will it come to this?

**D**EPRESSION follows stimulation, as surely as night follows day. The pendulum always swings back in the opposite direction.

Artificial stimulation of the salivary glands by an acid dentifrice, brings about a reaction which results in a period of salivary depression.

This is a fundamental physiological law. Normality and health demand a physiological dentifrice.

Colgate's Ribbon Dental Cream is not an acid dentifrice but a simple cleanser, efficient, harmless, pleasant to taste.

A generous supply of samples will be sent to professional friends, post-paid, on request.

## Mixed Benefits of Open Air

OPEN air schools are not an unmixed blessing and the results attributed to them are often due to the regular hours, good food, and medical care of the children rather than to fresh air itself assert Prof. William A. McCall and Bronson L. Huestis of Columbia University in *The Scientific Monthly*.

Until the recent era man was a troglodyte, a cave dweller. For eons ventilation was unknown. Less than a century ago the heavy canopied bed was in favor and the "miasma" of night air was a distinct phobia. Only modern man has regarded fresh air as a necessity.

The rapid spread of the open air school, its no abandonment record, the descriptions of its success, the rapid gain in weight of the children, the therapeutic value,—these, facts so often set forth are basis enough for the widespread belief in the efficacy of the fresh air school, assert the writers. In addition, it is claimed that the open air school makes education twice as efficient; it makes the children happier, improves attendance, and in some cases improves their truthfulness. Their popularity may be due in great measure also to the fact that they are a radical departure from the old type of school.

The writers' thesis is that the benefits which accrue to pupils in open air schools are not due to the open air primarily but to the regulated hours, good food, and good medical attention which children in the ordinary schools do not receive. The program of the open air schools begins at 8 a. m., when the children are served hot soup, and bread and butter. After every half hour they have vigorous exercise. At 10 a. m. they have two glasses of milk, bread and butter; at 12:30 a good dinner is served followed by sleep. At 4 p. m. they have milk, rye bread, and jam. At 7 p. m. they are given a good supper and sent home. The child in the regular school is in the school room from 9 to 12 and from 1 to 3. Medical, dental, and optical care received from the school authorities is inadequate.

Even experiments conducted to compare the advantages of the open air school as opposed to the ordinary school must be viewed with caution, the writers state. An open air test with the third and fifth grades checked with the same grades in the ordinary school was conducted for four years from 1912 to 1916 in New York City. Psychological tests and

physical examinations were made twice each school year. The results showed a slight balance in favor of the open air schools for which the writers feel that other factors might be responsible. The children who made up the open air group were given extra lunches and frequent outdoor play both of which were denied the other pupils.

In D. C. Bliss's experiment in Montclair, N. J., for which the same types of children were selected for both open window and control classes, the results showed no difference in the groups in the psychological tests but notable superiority in health for

the control groups, while in an experiment made the previous year in which the open window class was unprovided with the special lunch, the health of the children showed up even less favorably.

The use of washed and recirculated air by the New York State Commission on Ventilation in two New York City school rooms showed a 2 per cent greater progress in educational, psychological, and medical measurements for the pupils in the partly fresh washed air school room.

The writers favor open air schools, they state, mainly because they insure to the pupil medical inspection, good food, and sufficient exercise, all of which should be the privilege of all pupils in all of the schools.

## The Red Cross Health Nurse

IN THE remote districts of the Northwest, covering territories more than ten thousand square miles in extent, traveling by means of automobiles, and by horseback over rough trails are the Red Cross Public Health nurses. Alaska, Porto

authorities.

During the past year the Red Cross Public Health Nursing Service has nearly doubled. On July 1, 1920, 908 nurses were employed in 817 different places. A year later 1,267 nurses were employed in 1,240 different

American Red Cross.

"She goes (1,335 of her) into the mountains, into the rural communities and mining and lumber camps; sometimes on horseback, sometimes on foot, often on snow shoes, or in her trusty 'flivver'."

Rico, and the Virgin Islands as well as the forty-eight states of the Union know and benefit by the services of the Red Cross nurse.

The objective of these nurses is the care of the sick, the correction of physical defects, the improvement of the health of the whole family, and of the community. Employed for the most part by the chapters, they work in close cooperation with the country and state health authorities, and in many places have proved of such value to the community that they have been taken over by the public

places. Moreover, 400 chapters are ready to establish public health nursing service as soon as nurses can be found.

To increase the supply of these nurses the Red Cross since 1919 has appropriated \$240,000 in scholarships to enable graduate nurses to take a public health nursing course. The chapters have contributed almost as much for the same purpose. Every incentive is offered to develop a unified system of service through which community health can ultimately be achieved.

## Weak Arch and Flatfoot —

that need mechanical correction are very prevalent and frequently are associated with painful heel, callouses on sole, fatigue, nervousness, neurasthenia, physical exhaustion and rheumatic tendencies. Heavy people and those who are constantly on their feet and whose occupation requires them to assume a posture conducive to the weakening of the leg and foot muscles are usually victims of these complaints. The corrective treatment is simple. Remove predisposing causes such as short hosiery, improperly fitted or constructed shoes and have patient fitted to

### *Dr. Scholl's* *Corrective Foot Appliances*

which are scientifically constructed to relieve muscular and ligamentous strain, remove abnormal pressure and restore foot to usefulness. There are distinct types of appliances for each condition. All quickly and easily adjusted to any degree of elevation or curvature, assuring the physician dependable results.

Leading shoe dealers and surgical supply houses in every locality carry Dr. Scholl's Appliances and have also been instructed in Anatomy of the Foot and the proper method of adjusting the appliances to fit both foot and shoe.

## Rhythm, Music and Education

**M**ANY psychologists are writing on rhythm either as primarily concerned in the organization of mental stimuli or, secondarily, in its bearing on fatigue. At least one author (M. K. Bradby) presents the thesis that the logic of the unconscious mind is merely a correlation of rhythms, mental association and memory complexes, grouping themselves according to similarity of rhythm. Practically all the behavioristic psychologists concede mental superiority to the motor types, and physical education is advocated principally because it develops those muscular coordinations which favor integration and result in controlled and well ordered living.

The energy concept of mental processes is more and more emphasized and current theories of psychopathology are based mainly on energies pent up, persistent, and misdirected. It remained for Emil Jaques-Dalcroze, a teacher of music, to develop through eurhythmics a system of training which finds expression instead of inhibition and repression for the child's need for movement and recreation, as a necessary part of the

school education, and couples ideas, and singing and listening capacities with bodily movement. He puts practice before theory and discovers in irregularities of gait and difficulties of coordination innate mental capacities or incapacities. Esthetic sense is developed, and the technicalities of musical training are not given in unsuitable cases. The child of complete musical incapacity, however, he says is as rare and as easy to recognize and classify as cases of idiocy in general school work, or of criminality in everyday life.

In certain schools where this method of training has superseded stereotyped systems of physical gymnastics, health and the acquisition of balance have found a parallel in the broader educational achievement. The benefit to the personality of transposing into movement of the dynamics of emotion will be conceded by the psychologist. If at the same time mere instruction is replaced by the cultivation of temperament, artistic as well as utilitarian ends will be served. The method has value.

G. P. Putnam's Sons, 1921.

## Principal Causes of Death

The Census Bureau's Summary of Mortality Statistics, 1920, which will be issued shortly, shows 1,142,578 deaths as having occurred in 1920 within the death registration area of continental United States, representing a death rate of 13.1 per 1,000 population as compared with 12.9 in 1919, which was the lowest rate recorded in any year since the registration area was established in 1900.

The death registration area (exclusive of the Territory of Hawaii) in 1920 comprised 34 states, the District of Columbia and 16 registration cities in nonregistration states, with a total estimated population on July 1st of 87,486,713, or 82.2 per cent of the estimated population of the United States. The state of Nebraska was added to the registration area in 1920, so that at present the only states not in the area are Alabama, Arizona, Arkansas, Georgia, Idaho, Iowa, Nevada, New Mexico, North Dakota, Oklahoma, South Dakota, Texas, West Virginia, and Wyoming. The figures for the territory of Hawaii will appear in the report, but they are not included in this summary.

The death rate from pneumonia increased from 123.5 per 100,000 in 1919 to 137.3 in 1920. For chronic diseases of the heart the rate increased from 131.0 to 141.9; for cancer, from 80.5 to 83. Some of the other diseases for which the rate increased are whooping cough, measles, cerebral hemorrhage, congenital debility and malformation, puerperal fever, scarlet fever, and appendicitis. The fatalities caused by automobile accidents and injuries show an increase from 9.4 per 100,000 in 1919 to 10.4 in 1920.

A marked decrease is shown in the death rate from tuberculosis, which was 114.2 in 1920 as compared with 125.6 in 1919; also in the death rate from influenza, 71.0 in 1920 as against 98.8 the year before. The death rate from suicide declined from 11.4 in 1919 to 10.2 in 1920. There was a decline also in the rate for typhoid fever and in that for accidental drowning.

It is said that the busy bee, so often held up as a model of industrious work, actually works twenty minutes a day. The explanation of the great amount that he accomplishes is said to be in the fact of the perfect organization of the hive. Perhaps it would be wiser for us to emulate the bee's social organization more and his supposed industry less.—Goddard.

## Industrial Hygiene in Toronto

**A** SURVEY of general conditions of industrial hygiene in Toronto has been issued by the Associate Committee on Industrial Fatigue of the Research Council of Canada. The Committee on Industrial Fatigue was established by the Honorary Advisory Council for industrial and scientific research in the Spring of 1919 to consider to what extent fatigue is a factor in industry in Canada and to what extent it calls for scientific investigation, and to establish means for research, if this seemed desirable. The object of the survey was to investigate the general conditions of industrial hygiene in some one respective locality which would make available information both on the probable incidence of fatigue and on the practicability of conducting intensive research into its causes. Data were collected in Toronto to give the general attitude of employers toward industrial hygiene and the measures taken to promote it. Seventy-six plants were visited, including all of the large plants and some of the smaller.

On the whole there was found to

be a widespread recognition of the value of good working conditions, with very little recognition of the fact that "good working conditions" can be determined not vaguely and indefinitely, but very accurately by a knowledge of the laws that govern the human body. While there is an interest in the subject, there was found to be a lack of continuous and organized effort to promote it. Most of the welfare work, so-called, and the employment management, was done solely with the object of improving relations between employer and employees and "keeping the man on the job."

The report goes further into detail to discuss the factors which hinder the extension of industrial hygiene, conditions observed, medical service in industry, sanitation, occupational diseases, and lost time from sickness.

The Committee recommended that a specific piece of research be planned and that the whole question of occupational disease needs research into the effect of substances in use, with recommendations as to the best preventive measures.

## How the Right Shoes Increased Her Sales

*A true story with a lesson for all men and women*

"MISS GREEN, you and eight other girls out of seven hundred have shown increased sales during the last three months. All the others show losses. Why have you been able to increase your sales?"

"Who are the eight girls?" asked the young woman

The president of the store read the names. The girl seemed happy to answer:

"Shoes—Cantilever Shoes. I got them first. Later I took each of those girls, in turn, to the Cantilever Shop. In Cantilevers, you see, our minds are off our feet. The business gets all our attention. We don't feel cross, cranky or tired. I suppose that's why our sales are good."

That afternoon the president of the big store walked into the Cantilever Shop and asked a salesman to explain the features of Cantilever Shoes.

The Cantilever salesman took a shoe and bent the sole at the shank, showing how the shoe

conforms to the human foot, even to having a flexible arch like the foot. He said, "the arch of the foot should flex with every step, according to nature, yet ordinary shoes are made rigid by a concealed metal shank-piece that forbids free movement of the muscles. There is no rigid shank in Cantilevers. The 'waist' is designed to hug the instep, the shoe fits and supports the arch restfully. The flexibility allows the arch muscles free play and this, together with the natural lines of the shoe, permits perfect circulation.

"It is important to allow the foot muscles to exercise, to keep well and strong. The forepart of a Cantilever Shoe is shaped to look well, while allowing the toes to lie in their normal position. Cantilever heels are moderately high—high enough to be smart, without throwing the posture of the body out of balance as exaggerated heels do, causing unnatural pressure and strain on the nerves and the internal organs. By wearing Cantilever Shoes a woman avoids headaches and backaches, irritability and nervousness. She is brighter and happier."

"The subject is of great importance to the business woman who is required to stand during the greater part of the working period. The tired feeling often complained of at the end of the day's work may be attributed to ill-fitting shoes."

—Dr. Wilmer Krusen, head of the Department of Public Health of Philadelphia.

"Pain is a great foe to good looks. Comfort works just the other way. If you are comfortable, you are apt to be pleasant, and pleasantness and prettiness are often synonymous terms. Eliminate as many of your worries as you conveniently can—and your tight shoes."

—Grace Margaret Gould on "Good Looks" in Women's Home Companion.

"Working women are the worst offenders. It is the girls who are on their feet most who persist in wearing the highest heels. Sensible women have learned that they can increase their efficiency and even earn bigger salaries by wearing shoes built for 'cold comfort and health'."

—Dr. Evangeline W. Young, of Boston.

If no dealer listed at the right is near you, the Manufacturers, MORSE & BURT CO., No. 1 Carlton Avenue, Brooklyn, N. Y., will mail you the Cantilever Shoe Booklet and the address of a nearby dealer.

## Public Health in the 18th Century

Incidental to a discussion of the "Life and Writings of William Douglass, M.D., (1691-1752)," Dr. George H. Weaver in the current *Bulletin* of the Society of Medical History of Chicago brings out a number of interesting features concerning medical and public health work in America early in the Eighteenth Century. Boylston, Douglass, and Golden were the three conspicuous physicians of their generation. Douglass was the only physician in Boston with a medical degree, while Boylston introduced inoculation for smallpox, a procedure which was opposed by Douglass as a novel and dubious practice, insufficiently assured as to its safety and consequences. His position that there was danger of spreading smallpox through inoculation was well taken and his essay concerning smallpox is a brief concise statement of the disease.

In 1736 Douglass published a descriptive paper on "The Practical History of a New Epidemical Eruptive Miliary Fever," which was the first accurate clinical description of scarlet fever in English. In the absence of any medical school or hospital, he apparently became the teacher of the less favored members of the profession. He possessed the quality, common to most great men, of desiring to raise the standards of his profession. He favored the regulation of the practice of physics throughout the province and urged a plan for the appointment by the General Court of a board of physicians and surgeons who should examine all practitioners.

## Dental Work in Institutions for the Insane

When an individual is committed to the care of an institution under state, city or private management, it is assumed that he will receive every medical attention of whatever nature is deemed advisable by competent medical authorities, but this taken for granted proposition has not been applicable to dentistry, states Frederick A. Keyes, D.D.S., in a recent issue of *The Journal of the National Dental Association*. Dental societies, says Dr. Keyes, have been very lax in presenting to governmental agencies the importance of the care of the teeth to the general health of institutional communities. The enormous amount of work done in such institutions and what remains yet to be undertaken among the population temporarily or permanently confined in

institutions throughout the country calls for adequate equipment for first rate dental work. Figures are given showing the amount of work that has been done and also the status of the resident dentist as indicated by the salary scale of the employees at state institutions.

The science of dentistry and incidentally the science of medicine has suffered from the prevailing lack of system relative to indexing the physical condition of such patients subsequent to adequate dental care. The real value of such work is supported by available statistics relative to the incidence of infectious diseases, and at least one man, Dr. Cotton, claims to have established a definite relation between psycho-neurosis and oral sepsis. Dr. Keyes deplors the radical and excessive enthusiasm on the part of some dentists who claim that the teeth are the foci of infection which are the primary cause of the whole gamut of human diseases, but he urges the necessity for adequate dental care for all inmates of institutions, with such records as will bring out the scientific explanation of the relation of teeth to physical as well as to mental disease.

## Stammering and Its Correction

The general public is awakening from the illusion that if a child fails to develop normal speech there is nothing to be done in the way of correction. Correct habits of speech may be obtained by training. It has been estimated that 2 per cent of all children stammer. In Girard College, Mr. Leon Mons reports 8 per cent of the pupils as having defects of speech and about 4 per cent of these as stammerers. The new charter of Philadelphia makes speech correction obligatory. Training for speech is training for life, according to Mary Summers Steel in a recent issue of the *Pennsylvania Medical Journal*, and one of the anomalies of the educational world is that speech, the highest development within the possibilities of man, has been neglected or left to chance. The most important years for the training of speech are the first five years of life. Speech is an acquired faculty and stammering is an acquired defect, the result of incoordination of the mechanism of speech. The child generally begins to have trouble because he does not know how to combine the art of ideation with that of oral expression. He struggles to utter words after the mind has gone forward.

In discussing whether speech train-

ing should be physical or psychic, Mrs. Steel goes on to say that the best results are secured through education in the use of the peripheral mechanisms. After obstructions to normal breathing have been removed, all young children showing the slightest tendency to hesitate in speech should have daily training in correct active breathing for voice production. rhythmic exercises, and very distinct dictation of short colloquial sentences which the child may repeat.

## Eye Sight Conservation Council Elects

At the annual meeting of the Eye Sight Conservation Council held in New York, February 7, the following officers were elected: Director for three years, R. M. Little, director Bureau of Rehabilitation, N. Y. State Department of Education, Albany, N. Y.; general director, secretary and treasurer, Guy A. Henry, New York, N. Y.; finance committee consisting of Wm. A. E. Drescher, Rochester, N. Y.; Arthur Frank, New York, N. Y.; John H. Hardin, Chicago, Ill.; Charles R. Johnson, Mt. Vernon, N. Y.; and Dr. Frederick Willson, Reading, Pa.

Dr. Eugene L. Fisk, of the Life Extension Institute, addressed the meeting on the subject of "Fatigue." A paper on defective vision as a contributing factor to fatigue in industry written by Dr. Frank Gilbreth, industrial engineer, was read by Bailey B. Burritt.

## Mask Protects Eye Glasses

Underwood & Underwood.  
A new mask, suggested by the ordinary baseball mask, has been invented for basketball players who need to wear glasses while playing the game. The device allows plenty of room for the glasses.

# Sherman's Polyvalent Vaccines

A more adequate and rapid immunity can be established with polyvalent vaccines than from an infection itself. SHERMAN'S POLYVALENT VACCINES rapidly stimulate the metabolism and defense of the body with a resultant prompt recovery in general acute infections.

Given early, bacterial vaccines almost invariably cut short the common pyogenic infections of the skin, mucosa joints and tissues;

Administered in advanced cases, they usually ameliorate or abbreviate the course of the disease;

Even when used as a last desperate expedient, they often reverse unfavorable prognosis.

The immunizing powers of stock vaccines are demonstrated by the prophylactic efficiency of typhoid vaccine. Bacterins made from selected, vigorous organisms are far higher immuno-producers than autovaccines prepared from feeble, degenerated organisms sometimes found in the patient's own specimens. Especially in acute cases, the PROMPT injection of a stock bacterin is decidedly preferable to the DELAYED injection of an autogenous one. The place for autovaccines is in chronic infections which fail to clear up under stock bacterins due to the prob-

able presence of some unusual bacterium.

Advanced inflammatory processes due to only one class of bacteria are rare, mixed infections being the rule. Therefore, COMBINED VACCINES, containing all strains likely to be present, give the best assurances of success; an unneeded variety of the bacterin is harmless and in no way weakens therapeutic response.

Thus the favorite invaders of the nose and throat are the pneumococcus, the streptococcus, the staphylococcus and the micrococcus catarrhalis, calling for Sherman's No. 40, and in chronic cases—when there is a foul odor produced by the Friedlander bacillus—Sherman's No. 36. In visceral infections, due chiefly to the colon bacillus with the pus cocci, Sherman's No. 35 is appropriate. In Neisser infections, if these organisms are not already allied with the gonococcus, the imminence of their entrance is so great that the rational combination is Sherman's No. 49.

When, particularly in grave cases, valuable time may be lost in securing the variety of vaccine especially recommended, it is always advisable to use the vaccine at hand which contains the predominant organism of the disease to be combatted.

## Sherman's 10 Mil Container

This package has many superior features which assure asepsis, prevent leakage and facilitate the removal of contents. It is constructed on the well known Sherman principle.

The vial is amply strong which prevents breakage so frequent with shell vials.

We are exclusive and pioneer producers of Bacterial Vaccines. Originators of the aseptic bulk package. Pioneer in elucidation, experimentation and clinical demonstration.

Twenty Preparations.

Beyond the experimental stage.

**BACTERIOLOGICAL LABORATORIES OF  
G. H. SHERMAN, M. D.**

DETROIT, U. S. A.

"DAILY USERS OF VACCINES USE SHERMAN'S"

## Training in Psychiatric Nursing

In estimating the requirements of psychiatric nursing and placing a value on the training received by the average nurse to equip her for state institutional work, Donald A Laird, reports in the *American Journal of Psychiatry* an investigation made of the training offered in twenty-five representative state hospitals. The final averages show that only about one-tenth of the formal training received by the nurses is concerned with topics strictly related to the chief duties of a state hospital nurse. Normal and abnormal mental studies received 10.5 per cent of the time of instruction; occupations and recreations received but 2.4 per cent, while  $\frac{1}{2}$  of 1 per cent of the courses is devoted to social service and mental hygiene. Mr. Laird's criticism is that the state hospital training schools follow entirely too closely the same plans and courses as the general hospital schools and that in most cases the final product is poorly trained for both mental and general nursing. Psychiatric nurses should receive psychiatric training. They should be registered nurses as well and their special work should be so organized as to bring desirable candidates in large numbers to psychiatric training schools. An inquiry into the content of the psychiatric courses revealed the fact that none of the curricula studied present the subject; none of them has a presentation of the psychology which will go far toward giving the nurses a working basis for psychologizing for themselves. Mr. Laird goes on to say:

A grave danger lurks in a psychiatric course which deals mainly with types, pathology, and emergencies. When no comprehension is received of the mental mechanisms operative in all psychoses, normal and pathogenic, the nurse still retains the popular conceptions of mental disorder with which she entered the service of the state hospital and sees in insanity the results of degeneracy and inferiority at least. The modern conceptions of mental disorders recognize other factors than the purely organic as being operative in the genesis of unusual mental states. When those engaged in the immediate care of mental patients receive enlightenment along lines that will undermine their superiority psychosis the case histories will contain fewer records of othematoma and related effects of the psychiatric content now in vogue in the State Hospital Training School.

An extended treatment such as would be required to cover adequately the topics necessary to convey to the nurse working conceptions concerning the psychoses and neuroses would ob-

viously take more time than is now utilized in giving clinical epitomes. But since the psychiatric nurse should receive the training that will best fit her to be of most service in the patient's adjustments, sufficient time can be found in the ordinary course of study by maintaining a proper balance between the essential and the auxiliary courses.

## The Adolescent Girl

The health problems of the adolescent girl are developed and explained in a recent popular publication of the Child Welfare Organization of America, entitled "My Health Book." The rules of the game of life are enumerated and the right of the young and growing girl to be filled with energy and ambition is emphasized. It is imperative that at least once

a year there should be a physical overhauling, complete and thorough, in order to ascertain whether the machine is in good working condition, and any discoverable defects, which should be at once corrected. Perhaps the most important feature is the determination of weight. Underweight, if marked, is a departure from health which should be recognized. It is an indication of malnutrition, caused sometimes by food improper in kind or insufficient in amount. It may be the result of bad conditions of work, bad surroundings, bad habits of exercise, and rest or play. In order to reach the highest levels of health and efficiency and power for service, a girl must carefully study the question of diet; her teeth must be in order; her eyes, skin and feet in condition.

## Study Rickets Among Italians

THE deplorable amount of rickets among the Italians, who, in their own country are normally freer from this disease, suggested the analysis of dietary and living conditions of Italian immigrants to discover the etiology of the condition. This subject was the subject of a recent investigation among Italians in Boston reported by Dr. Bessie Talbot Strongman and Dr. Henry Ingersoll Bowitch in a recent issue of the *Boston Medical and Surgical Journal*.

The handicaps of the rachitic are too well known to need comment. Its control as a measure of pelvic deformity in women would of itself be of great economic value and its influence is considerable in causing chest deformities, which are contributory to subsequent respiratory disease.

While the figures in this study are inconclusive as to racial predisposition, crowded and dirty living quarters, lack of sunshine, or diet of low energy quotient appear to affect the Italians more unfavorably than Hebrews and Poles, for instance. The susceptibility of Italians to rickets is characteristic only of city dwellers, suburban Italian communities showing little rachitic deformity. The suburban population doubtless get more green vegetables, potatoes and milk and have better living conditions.

Certain characteristic habits and tendencies are fairly widespread among Italians. Early marriages give a maximum child bearing period with little attention to prenatal care. Nursing is unduly prolonged. There is but little discipline. When the child is finally weaned, it is immediately

placed upon adult diet. Spaghetti, macaroni and white bread are the main foods, all of a highly milled wheat and lacking in vitamins. Moreover, the macaroni is frequently undercooked, and is habitually served with oil, a practice which delays the splitting up of the starch in the digestive process. The fats employed are increasingly cotton seed substitutes, which is entirely deficient in the fat soluble vitamins. Meats are sparingly used and meat fats are employed in negligible quantities. Milk is unpopular among the Italians in Boston.

There exists, then, a deficiency of vitamins and proteins, which may for economic reasons become extreme, as many of these people have families out of proportion to their incomes. The mothers are very busy with their large families; the day's fare is often provided in one kettle into which is placed what they have in the house, not following any given recipe and without regard to food values. The younger children are apt to be the more rachitic, and maternal fatigue may constitute a factor. The housing is unfortunate, as families, already crowded, often make room for a boarder. These mothers cannot be induced to give up their Italian cookery for the detested oatmeal. Trained workers, therefore, are needed to devise diets which are known to the Italians and are palatable to them.

Domestic science courses for the women and children, better adaptation,—Americanization, if you please,—will eventually eliminate the rolling rachitic gait of these Italian children.

## Yeast in relation to dietary deficiencies

THE constant need for a sufficient supply of water-soluble vitamine in the diet is now well-known. Physicians are aware that general debility and susceptibility to miscellaneous infections follow the continued ingestion of food containing too little of this dietary factor.

Yeast is richer in the water-soluble B vitamine than any other known substance—in laboratory experiments it was found to be four times as efficient as dried spinach.

"A scrawny, lethargic animal, rapidly dwindling in size, with unsleek coat and evident malnutrition, will completely change its appearance and responses in a few days at most on a diet unchanged except for a tiny bit of yeast"—that is the description given by one of the foremost physiological chemists of America.

In experiments carried on at the Laboratory of Physiological Chemistry of Jefferson Medical College the ordinary household yeast (Fleischmann) was utilized as a source of vitamine and was found to have very important properties.

The American Journal of Physiology (vol. xlvii, no. 2) has an interesting report on this test of yeast in remedying dietary deficiencies. Young white rats, starv-

ing on a diet of beef, butterfat, casein and starch, given the same diet plus 5 per cent Fleischmann's Yeast showed gains as high as 100 per cent in fourteen days.

The success of these and similar experiments has given impetus to the study of yeast. Physicians are now prescribing it for certain dietetic troubles, and the yeast treatment, both in hospitals and in private practice, has been attended with marked success.

Fleischmann's Yeast offers an easily obtainable, economical, and scientifically standardized source of vitamine. It is obtainable fresh daily, from grocers, or if the physician prefers he may write The Fleischmann Company in the nearest large city and it will be mailed direct on the days wanted.

Usual dose one cake administered, t.i.d., plain, or in suspension in water, fruit-juices, or milk. As whole milk is a rich source of the fat-soluble A vitamine the dosage with milk insures a bountiful supply of both vitamins, a very favorable combination in correcting deficient diets. Yeast may be taken with meals or on the empty stomach. If the patient is troubled with gas formation, dissolve the yeast in boiling water before administering or administer living yeast between meals.

## Czecho-Slovakia Gives Builders State Aid

A new law has gone into effect in Czecho-Slovakia which grants state aid to builders of dwelling houses. The law permits the requisition of public land for private building purposes, and, under some conditions, of land owned by individuals, and provides for a court of arbitration, consisting of representatives of both workers and employers. This court also decides all conflicts between building workers and employers. Other courts are provided to fix the prices of building materials. The state is to subsidize all dwelling house construction done in 1921 and 1922. All new permanent dwellings are to be free from taxation for fifty years; the builders of temporary buildings intended to last at least twenty years will receive subsidies amounting from 40 to 60 percent of the total cost of construction.

To obtain funds for this undertaking, the state is to issue lottery bonds up to the amount of one billion dollars. About one-sixth of this amount is to be used in building houses for government employees.

A summary of an article on "Housing Measures in Czecho-Slovakia," by the Czecho-Slovakian minister of social welfare, published as an appendix to a report of the United States Department of Labor on the economic condition of that country in 1920, was published in the *Monthly Labor Review* recently.

## Hygienic Rites Practiced by Savages

The African savages, who polish their teeth to ivory whiteness with the chewed ends of sticks, may be greatly deficient in many ways, but in their extremely careful observance of this hygienic rite they serve as examples to many civilized people, is a statement contained in a "Tooth Talk" in a recent issue of *Public Health*. The editor goes on to say:

The proper care of the teeth is quite as essential to the well being of the body as the unceasing vigilance of sentries is to a beleaguered army. The mouth gives access to infection. Unless the teeth are kept clean they will become infected and decay. Tiny particles of decomposed food remain between the teeth and create an ideal breeding ground for germs. When this condition exists these pernicious little enemies find their way into the blood through which they circulate to all parts of the body.

They likewise promote the decay of the teeth, which means the breaking down of an essential part of our phys-

ical machinery. Proper mastication of food is essential to good digestion and broken, ill-kept incisors, bicusps and molars do not make satisfactory cutting and grinding machines. As a result, unfair demands are made upon the digestive systems and trouble is apt to ensue.

With dentistry in its present high state of development, there can be but one excuse advanced for rotting, ill-kept teeth,—carelessness.

Begin with the children at an early age, and teach them to clean the teeth thoroughly at least twice a day, morning and evening. Do not excuse neglect in the care of children's teeth by the fact that the first or temporary teeth will be replaced by others. Their present health, the prevention of decay and its accompanying pain, and the formation of the essential habit of cleanliness in these early years make the care of children's teeth a matter of the utmost importance.

This care is equally essential to the health of adults. Numerous serious ailments can be traced directly to bad teeth. There is another distinct advantage to be derived from proper tooth care. How cheerful an introduction is the smile which displays a row of sound teeth. It seems to bespeak cleanliness, healthfulness and self-respect.

## Dirty Milk Responsible for Many Deaths

Milk is one of the most important and valuable of human foods, says a recent editorial in *Public Health*.

It is indispensable to rich and poor alike, the one standby of man through all the ages of life—infancy, youth, maturity and old age. Yet in spite of its importance and qualities, milk may be a most dangerous carrier of disease. There is not a single article of food which requires more careful attention and handling than does milk. Its white cloak, instead of denoting purity, often serves as a shield for the concealment of dirt and infection. Milk is an admirable food for germs, as well as for human beings, and consequently when infected is usually more dangerous than infected water or food. Among the diseases which are spread by and which have been definitely traced to milk are typhoid fever, scarlet fever, tuberculosis, diphtheria, septic sore throat, and diarrhea and enteritis. The last two named diseases alone are responsible for more than 65,000 deaths among children under two years of age, in the United States each year. Dirty milk is directly responsible for a large proportion of these deaths. The mortality among babies fed on cow's milk is ten times that among those nursed by their own mothers. The result is not due so much to the phys-

ical difference between the cow's milk and the mother's milk, as to the disease germs and filth which find their way into cow's milk. To have safe milk, we must have clean milk. To insure clean milk, we should observe these requirements: Healthy cow, clean and careful milking, proper and sterile containers.

## British Chief Medical Officer Issues School Report

That 70 per cent of the school children of England and Wales need dental treatment was disclosed in the annual report of the Chief Medical Officer of the Ministry of Health for 1920. Two-fifths of the children coming up for inspection were found to be suffering from defects. From five to seven per cent had diseased adenoids and tonsils requiring surgical treatment. Illness was found to be the real or alleged cause of most cases of absence.

That summer time is not detrimental to the health of children was the conclusion reached after a study of the effect of the Summer Time Act.

During the past year, the school medical staff has increased from 224 whole time officials to 800. In addition many school nurses and regular physicians have been employed. Approximately 2,400,000 children were examined in three groups—entrants, 8 year pupils, and leavers. Secondary school inspection has now been made compulsory also.

## Device to Aid the Armless

Keystone View Co.  
Major MacLure, an English inventor, has perfected a device for the armless which enables them to read and turn over pages, paint, sketch and write. He is distributing them free of cost to London hospitals.

# KOTEX

## *Lessens the Laundry Problem*

**K**OTEX are cheap enough to throw away, and easy to dispose of instantly by following directions found in every box.

Kotex is so easy to obtain at drug, dry goods, and department stores. No unnecessary counter conversation. Simply say, "A box of Kotex, please." They come in Regular size and Hospital size. The Hospital size is extra large, and therefore adequate for any emergency.

Kotex, once used, form a new sanitary habit. They are unsurpassed at business, when traveling, or at home, and a supply should always be kept on the shelf.

Kotex are very well made of fine gauze and Cellucotton—a wonderful sanitary absorbent now used in most leading hospitals. Extra long tabs for secure and comfortable pinning. There is no explanatory printing on the blue box, merely the name Kotex.

Kotex solves a difficult laundry and hygienic problem.

Cellucotton Products Co., 208 S. La Salle St., Chicago  
51 Chambers St., New York.      Factories: Neenah, Wis.

*Regular Size, 12 for 60c  
in Canada 85c*

*Hospital Size, 6 for 45c  
in Canada 60c*

Sample of either size mailed  
in plain wrapper for 10c.

*Kotex cabinets are now being installed in women's rest rooms everywhere — hotels, office buildings, restaurants, theatres and other places from which may be obtained one Kotex with two safety pins, in plain wrapper for 10 cents.*

## The Instincts and the Unconscious

Just as physiologists have been interested in ascertaining the biological background of organic development and function, both in man and in the lower organisms, so are psychologists finding in mental reactions traces of the record of racial experience and in the psycho-neuroses an expression of the pathologic recurrence of modes of action formerly useful, but normally long displaced by the more recently developed conduct of a higher order and therefore subject to a more unstable control. Disregarding the sex implications of the Freudian scheme, its many useful features are employed in explaining the psychic mechanisms by which the experience is sorted, sifted, secured, or suppressed, according to its compatibility with the main body of the individual experience, according to the satisfaction or dissatisfaction afforded, or to the degree of effectiveness as useful reaction.

The morbid aspects of the human mind, especially the illuminative cases brought out by the psychoses of warfare, have served to emphasize the importance of the content of the unconscious mind, and the great mass of literature growing out of war experience bids fair at last to develop a common body of psychological principles and measures for the handling of the cases of nervous unbalance encountered in civil practice, measures which correspond with proved and accepted practice in medicine and surgery.

This book by W. H. H. Rivers is a substantial contribution to the biological theory of the psycho-neuroses. After a series of analytical chapters on the unconscious, suppression, repression, dissociation and inhibition, hypnosis, sleep, and hysteria as the various means by which the human organism attempts to solve the conflict between re-aroused instinctive tendencies and the forces by which they are normally controlled, Rivers concludes with a treatise on the process of sublimation as a therapeutic agent, this process often involving re-education. Whether the outcome of such conflict and such re-education be genius or paranoia depends upon the measure of re-direction it is possible to give the misdirected energy.

The energy concept of mentation is maintained throughout, psychic as well as physical reaction being conceived to operate under the dynamic laws

which govern everywhere the transfer and transformation of energy. It is to be noted that the perfect mental adjustment which spells complete stability is a non-productive state.

Instability in this book has been considered in its rôle as the producer of disease; but the inevitable conclusion is that we must likewise look to the unstable types as the source of the energy from which accrues the great accomplishments of art and

science, and as the motive power of those great movements which express the universal craving for human betterment. One is reminded here of the parallel between the periodic table in physics in which the stable elements must be regarded as end products of energy expended, recombinations and predictable changes being looked for where the net force is in disequilibrium.

Cambridge University Press, 1921.

## Industrial Fatigue and Efficiency

THE problems of industrial fatigue, its measurement, control and influence upon efficiency have been developed recently by Dr. H. M. Vernon, the investigator of fatigue for the British Research Board in his recent book "Industrial Fatigue and Efficiency." Fatigue is defined as a "diminution of the capacity for work which follows excess of work or lack of rest, and which is recognized on the subjective side by a characteristic malaise." The sense of fatigue may be regarded as subjective or objective in character and special attention is here paid to the objective side of the situation, that is, the capacity for work. Subjective fatigue tends to be cumulative, reacting upon the health of the worker, for if one's health gives away the productive capacity of the worker may be entirely lost until his health is regained.

One of the most important objects of fatigue studies is the determination of the influence of the fatigue induced by an industrial occupation on the health of the worker. Although fatigue occurs, it may not be sufficiently severe to be regarded as pathological. The results of cumulative fatigue may be delayed for weeks, months or even years. The occupation itself or the conditions under which the work is performed may be the cause of fatigue. It may arise from the occupation *per se* or may be the result of the conditions under which the work is performed. It is unreasonable to suppose that the worker's entire energy will be expended upon his industrial labor. Other interests, recreation, and amusement should be a part and parcel of his life. The worker has a certain supply of energy each day and the more he spends on wasteful or unnecessary tasks the less he has for useful ends and the more his efficiency is reduced. To the degree that fatigue is avoided or eliminated,

the efficiency of the worker is increased, and the object of industrial efficiency is to obtain a maximum production with a minimum of effort.

It is impossible in a limited space to do justice to the painstaking effort and careful observations which Vernon has gathered together. The study of hourly, daily and weekly output and hours of work in the various industries, the six hour day and multiple shifts, rest periods, lost time, limitation of output, sickness, accidents, mortality, etc.—all receive a keen analysis with a factual basis heretofore lacking in so many discussions.

In concluding his analysis Dr. Vernon has outlined certain general principles which should be adopted. First of all the employer must have healthy factory conditions, "adequate lighting, heating and ventilation of workshops, washing facilities, cloak rooms or ambulance room, and if possible a well found canteen." The selection and arrangement of work spells, meal breaks and rest periods is of great importance depending in large part on the decisions of the employer. Saturday half-holiday, public holidays, and summer vacation are indispensable.

It is also of great importance that individual factories and industries collect and study data on their problems systematically. Accident data should be divided into different categories and classified by the sex of the worker, the time of their occurrence, and possibly a separate classification of accidents incurred. Sickness records must be more exact and the output of piece work should be tabulated and classified from time to time to check up restrictions of output. The questions of scientific management and vocational selection have not been developed inasmuch as they are really individual fields independent of the present study.

## A Dignified Service

Few periodicals of any type have developed a classified advertising standing equal to that of THE MODERN HOSPITAL.

It is a unique achievement. Hospitals and people in the hospital field have, by their repeated use of our columns, broken down the impression that want ads are undignified.

Have you tried a classified advertisement in THE MODERN HOSPITAL to help you dispose of some used article? It has served many superintendents very successfully in this way.

Let the classified advertising columns of THE MODERN HOSPITAL be of service to you.

## A Social History of the American Negro

A history of the negro people tracing their problems and difficulties from their African habitat, through their development in America, the system of servitude, the progress of slavery, the gradual rise of consciousness, organization and leadership, has been published recently by Benjamin Brawley. About 1830, with the Abolitionist agitation the challenge was thrown to the slave holders. This discussion of slavery was not peculiar to America, it was part of the world wide attitude, the problems of the negro were for some time afterwards largely incidental, at least so far as the general public was concerned. But the negro race was gradually gathering momentum. Nat Turner's insurrection called instant attention to the great moral and economic problems involved in slavery, definite lines of cleavage were marked out and the hopes for compromise disappeared. The third period or epoch with which the author deals extends from the Civil War to the opening of the Great War. The thirty years from 1865 to 1895 the author says "may be regarded as an era in which the race, now emancipated, was mainly under the guidance of political ideals."

The term "political ideals" is used loosely here, although politics in its popular and most savory sense may have been present always, ideals seem conspicuous by their absence. It might be said that the period of adjustment was rather more determined by social and economic than political factors. Politically, so far as the nation is concerned, the race was free. Federal troops were withdrawn in 1876, local force followed by mechanical devices such as the so-called Grandfather's Clauses, did not develop until somewhat later in Mississippi about 1890. These disturbances developed first from the lack of administrative facilities for the enforcement of the equalitarian doctrine declared and secondly, as has been said from the attempt at social and economic readjustment, unplanned and unsupervised.

The second part of this period 1890 to 1915, from the point of view of the contemporary observer is most interesting and instructive. Unrest and violence are found but solid economic and social progress was made under the leadership of such men as Booker T. Washington. The progress

of a race against prejudice and calumny is astonishing and inspiring. If the future is to be interpreted in the light of the past, these barriers will drop. We who seek to inspire the world with thoughts and aspirations might well turn to our own back yards and set our own houses in order. The author pleads modestly for a campaign against lynching and some of the other outrages. Can we accomplish international peace when interracial peace in our own life is far afield? Although we have come a long way, there is a long way to go, and only the intelligent analysis and planning of a controlled situation can clear up some problems. "The negro problem is only an index to the ills of society in America."

### The Stages of Human Life

How are we physiologically to perform the continuous duties of a healthy citizen, and, secondly, how is this to be extended to succeeding generations is the theme of J. Lionel Taylor's study of "The Stages of Human Life." His material is divided into three general subjects, personal, public and racial hygiene, the last being termed also eugenics. The present book is an attempt to show that each age or stage of life has a distinct contribution to make and it is our business to live most effectively each stage. In a popular style much of the material relating to public health of current vogue is developed and reinforced with quotations from various literary lights from Aristotle and his confrères to Sir William Osler, omitting, we regret to say, Mr. H. G. Wells and his cinema of history, certainly a grave omission.

E. P. Dutton & Co., New York, 1921.

### Medical Charitable Service

THE Director of Charity (Conseil Supérieur de la Bienfaisance) Belgium, has published a report or study on "The reform of Charitable Medical Service" by Dr. René Sand. This reform of medical service in fact presents two aspects: First, it covers as a corollary to the universal reform in charitable relief which has been in progress more than a half century, and, second, as a result of the increased interest and concern with regard to safeguarding public health. So far as the service is concerned, as pointed out, the point of view of the individual and of the groups is convergent, the problem being first to

apportion among the sick and indigent a service prompt, efficacious and more certain; and then to preserve and to improve the capital of health and productivity which is the richest force of a nation. To this end, scientific organization has replaced empiricism, preventive work superseded curative or remedial work.

A commission was organized in 1895 to study the situation reporting in 1900. Of the various reforms which it recommended but one has been realized, the creation of a Superior Council of Charity, in May 26, 1912. Since the armistice the question has been revived and as a result of legislative enactment this report is made. The study is limited to Belgium, in which, as in many other countries, the same methods of reform, the same solutions have been offered and realized. The war also made a virtual revolution in surgical and medical fields, dependent in large part for its success upon hospital facilities. The report is divided into four parts: (1) the description of actual medical charitable service; (2) an explanation of those reasons favoring reform in medical service; (3) proper methods of improving the service in the home, medical, hospital, pharmacological fields, etc., and administrative reforms for the charitable service; and (4) the conclusions of the Conseil, the general plans for reform and the measures to be immediately applied. The appendices attached contain articles on the disposition of medical aid, and the questionnaire of Dr. Sand.

### Makes Plea for Rural Life

Mr. C. T. Wing, the representative speaker at a conference of the National Union of Teachers at Bridlington, reported in the *Lancet*, London, of April 16, 1921, makes a plea for rural life and the open-air school. "It would pay local authorities to scrap all school buildings in the center of the cities and to build on the outskirts, where the winds blow, the flowers grow, and the birds sing," he says.

### Colombia School Inspection

By a decree of the National Government, the Inspector of Public Instruction is charged with the duty of making frequent visits to the secondary and professional schools of Bogota. He is to supply complete statistics of the progress of education to the ministry of education, reports the *Bulletin of the Pan-American Union*.

## FROM THE FIELD

Volume I of the history of Great Britain's medical service during the war has just been published. This is the first of four volumes dealing with the general history of the medical services. They will be followed by eight more volumes covering the fields of surgery, hygiene, pathology, tropical medicine, etc.

Ten new centers for the medical and dental treatment of school children attending London Educational Committee Schools are to be opened during 1922-23 according to reports contained in *Health* (London). Four of the centers will treat minor medical ailments, and the remaining six will be in the nature of dental clinics.

The hospitals of Richmond, Va., for the first time in the history of nursing education in the state, have combined to offer a course of lectures in public health nursing, tuberculosis, community sanitation, and public health. The lectures are being given by the Richmond School of Social Work and Public Health and are made possible by an appropriation made by the Richmond Tuberculosis Association.

The American Electrotherapeutic Association and the New York Electrotherapeutic Society held a joint mid-winter clinical session at U. S. Public Health Service Hospital No. 61 at Fox Hills, Staten Island, N. Y., on December 29 and 30. A two days' demonstration of physical therapeutics open to physicians generally was held during this meeting under the auspices of the U. S. Public Health Service.

Representative Lester D. Volk of New York has introduced two resolutions in Congress dealing with narcotic drug addiction in the United States. One resolution directs the Secretary of the Treasury to furnish facts concerning a recent ruling of the Internal Revenue Department which would deprive addicts of the treatment and advice of their physicians and compel them to enter penal institutions and private sanitariums for treatment. The other calls for an investigation of the entire subject of drug addiction.

More persons were sent to the insane asylums in the State of New York than in any previous year, according to the report of the State Charities Aid Association recently submitted to the state hospital commission. At the close of the year 1921, 39,736 patients were inmates of the thirteen hospitals for the insane, an increase of 1,445 over last year. The increase in insanity is attributed to unemployment and distress caused by economic conditions. The establishment of occupational schools in connection with state hospitals was urged as a valuable therapeutic measure.

Mortality from organic diseases of the heart reached a total of 124,000 during the past year in the death registration area according to figures just published by the Bureau of Census of the Department of Commerce. If that part of the United States not in the registration area had as many deaths in proportion, the total mortality from cardiac disease would be 151,000. The highest rate from organic disease of the heart for 1920 was 180.8 per 100,000 for New York state and the lowest was 87.3 for Kentucky.

The Department of Commerce, through the Bureau of the Census, announces that within the birth registration area of the United States, 1,395,523 births were reported among the white population and 103,976 among the colored in 1920, and that the birth rate per 1,000 females was 48.2 for the white and 52.8 for the negro. The registration area includes 23 states and the District of Columbia and comprises 62.3 per cent of the total white population and 37.2 per cent of the total negro.

Dr. Eugene R. Kelley, State Commissioner of Health of Massachusetts, is sending out letters to expectant mothers to supplement the advice of the attending physician. These prenatal letters are available for physicians or others interested. Monthly post-natal letters are also sent to mothers until the child reaches the age of one year. This is an effort on the part of the Massachusetts State Board of Health to reduce maternal and early infant mortality and morbidity.

The Commonwealth Fund of New York City will finance for five years a program in methods of preventing delinquency and has made an appropriation of \$165,000 for the first year's work. Constructive and experimental activities will be conducted under a joint committee by the New York School of Social Work, the National Committee for Mental Hygiene, and the Public Education Association.

While the function of issuing employment certificates to minors has been transferred from the New York City Department of Health to the Department of Education by an amendment to the compulsory education law and labor law, the health department still maintains its protective guardianship over the child's health and all children applying for certificates must pass a physical examination given by it.

A system of industrial insurance for the entire force of workmen has been established by the board of directors of the National Railroad Lines of Mexico. This insurance is to be paid from the surplus receipts of the railroads without depriving the employees of any of their salary. The amount of insurance will be proportionate to the position, salary, and length of service of the employee.

*Better Times* (New York) comments editorially on the fact that for three years the East River Recreation Pier at the foot of Twenty-fourth street has been used as a storage house for street cleaning machinery while 15,456 children, mothers and fathers in the twelve city blocks in that district have wilted in the city's heat. The docks were turned over by the city to the government during the war for the storage of naval supplies and following the war were assigned to the city department of streets. The Pier is fully equipped for its original recreational purpose. Social workers hope to have it turned back to the people by summer.

A field study of the conditions under which children are prepared for and directed into industrial life is being carried on by the industrial division of the United States Children's Bureau in cooperation with the Junior Division of the U. S. Employment Service. The work of various agencies in fifteen cities is being studied intensively.

## Radiant Heat vs. Convective Heat

In industrial as well as private practice there is frequent need for the application of heat, particularly in such cases as neuralgia, neuritis, sciatica, mastoiditis and rheumatism.

The common practice was to employ some form of convective heat such as poultices, hot-water bottles, jacks, etc.

Today the profession recognizes the greater benefits derived from Radiant Heat, particularly as exemplified in

### The New Thermolite

This new method of heat application insures deeper penetration, resulting in a marked hyperemia, with a decided sedative and analgesic effect derived from reflex action on the peripheral nerve endings.

The new Thermolite radiates only parallel rays, with no focal point to cause burning.

The outer twelve-inch aluminum reflector contains a highly polished parabolic projector which in conjunction with a special 375 watt 120 volt lamp furnishes a parallel penetrating beam of correct intensity that covers an area of about 300 square inches at operating distance (36 inches from reflector).

A booklet illustrating The Thermolite in more detail will be sent free upon request.

**H. G. McFADDIN & CO.**

## 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

The Bureau of Jewish Social Research, 114 Fifth Avenue, New York, has been formed by the amalgamation of the Bureau of Jewish Statistics and Research, the Field Bureau of the National Conference of Jewish Charities, and the Bureau of Philanthropic Research. Samuel A. Goldsmith is the director.

Jersey City, N. J., has a new health center located at 123 Grand Street, the gift of Henry A. Colgate.

Slow-thinking pupils in German schools have had their intelligence considerably quickened by the administration of thyroid preparations. Medical research has shown that backward pupils are suffering from a hypo-functioning of the thyroid gland. Psychological research under the direction of Erich Jaensch, professor of Philosophy, University of Marburg, has discovered an entirely new world of juvenile mental activity, that of intuitive images. This ability to reproduce or clearly perceive intuitively is of great importance in building up a child's fund of concepts and perceptions.

Three studies of the physiological cost of muscular work appear as follows in the *British Medical Journal*. "Physiological cost of muscular work measured by the exhalation of carbon dioxide," by A. D. Waller and Miss G. De Decker, *Brit. Med. J.*, 1921, I, 669-71; "Physiological cost of muscular work," by L. Hill and J. A. C. Campbell, *Brit. Med. J.*, 1921, I, 733-4; "Estimation of the physiological cost of muscular work," by J. B. Orr and J. P. Kinloch, *Brit. Med. J.*, 1921, II, 39-40.

The largest mass of data on the heights and weights of children under six years of age ever brought together in this country has just been made public by the U. S. Department of Labor through the Children's Bureau. These records form a basis for measuring future progress. Of the 172,000 records tabulated, 167,024 were those of white children, and 4,976 those of negro children. Children in rural districts slightly exceeded the average for city children in both stature and weight. California children were found to be both taller and heavier than other groups in the study. Boys under six averaged one-third to one-half an inch taller and one pound heavier than girls of the same age.

Kenilworth, Ill., is cooperating to the fullest extent with the Illinois Board of Health in urging that every case or suspected case of communicable disease in the village be reported to the village health officer. Letters to this effect accompanied by a complete list of reportable diseases have been sent to every householder.

A resolution requesting the delegates to the Conference on the Limitation of Armament to call an international conference to suppress and regulate the commerce in drugs has been presented to Congress by Representative Julius Kahn, chairman of the House Committee on Military Affairs. The resolution was referred to the House Foreign Affairs Committee which is making an investigation of the international traffic in habit-forming drugs.

Industrial, engineering, and educational agencies are linking their efforts in a nation-wide movement for conservation of eyesight according to a report in the *New York Times*. Investigation in New York and London schools shows evidence of positive correlation between defective vision and retarded scholarship. In the London survey in which 32,000 boys and 29,000 girls were examined, it was shown that vision was progressively better with the progress of the children in scholarship, with the cases of bad vision relatively more frequent among the backward children. The investigation of the American Engineering Council's Committee on Elimination of Waste in Industry shows that heavy economic losses to industry and many accidents are caused by workers with defective vision.

The United States Bureau of Education is acting as the coordinating agent of the movement. U. S. Commissioner of Education Dr. John J. Tigert has been elected a member of the Board of Counselors of the Eyesight Conservation Council of America with headquarters in New York City. The following men are engaged in this work: Dr. Arthur L. Day, director of the Geophysical Laboratories of the Carnegie Institute, Washington; Dr. Thomas D. Wood of Teachers College, Columbia University; Dr. Allan J. McLaughlin, United States Public Health Service, Washington; Dr. Frederick R. Green, secretary of the Council on Health and Public Instruction of the American Medical Association, Chicago, and Dr. W. S. Rankin, state health officer of North Carolina.

"Making Work Fascinating as the First Step Toward the Reduction of Waste," was the subject of an address by Walter N. Polokov, consulting engineer, at the annual meeting of the American Society of Mechanical Engineers in New York City. Welfare work which diverts the worker's mind from his work, which acts as a 'spiritual cocain,' is directed along the wrong course, said Mr. Polokov. Such welfare work admits that there is no interest or satisfaction to be found in industry and that entertainment must be found outside of industry.

A wage of \$14.50 for a 48-hour week has been established as the minimum wage in the public house-keeping industry in the State of Washington. The daily wage set is \$2.50 for eight hours and the hourly minimum is thirty-five cents. Uniforms are to be furnished and laundered by the employer.—*Consumers' League Bulletin* (Cincinnati).

Milan, Italy, maintains a complete system of medical inspection for school children including examination by a school physician of each child before admission to school; inspection of school buildings and visits to every school once a week by the physician to examine the children and prescribe needed treatment; maintenance of a dispensary open three times a week in every school district; maintenance of clinics where children may receive free examination by specialists and free treatment where they cannot pay. Since 1918, visiting nurses have been employed. The city also maintains special classes for mental defectives, cripples, for children afflicted with trachoma or defects of hearing or sight, and an open air school. Special attention has been given to any possible effects of the war on the health of children whose fathers were in the service. The work of the city is described in a municipal bulletin.

The Michigan Department of Health, Lansing, announces the publication of three numbers of its reprint series which may be obtained upon request. The series includes: "Comparative Studies of Diphtheria Cultures of Loeffler's Medium with the Original Swabs Transported by Mail," by C. C. Young and Minna Crooks; "The Wassermann Test and its Interpretation," by R. L. Kahn, and "The Review of the Hillsdale, Mich., Typhoid Fever Epidemic of 1920," by R. M. Olin.

## The American Dollar and "AMERICAN" Sterilizers

An advertisement worth the reading of any interested in the purchase of sterilizing equipment—and directed particularly to those seeking the most for their expenditure.

WITH all eyes centered upon Price, the purchasing power of the American dollar has never been so taxed as it is today.

We sense that you are not immune to the price appeal in the purchase of your equipment. You are seeking the very most your money will buy—and rightly so. It is, therefore, a source of keen satisfaction to us to know and be able to prove that

### Sterilizers and Disinfectors

at present prices represent the greatest Sterilizer and Disinfecter value obtainable. Notwithstanding the fact that they cost more to manufacture, due to the use of finer materials, more searching tests, more scientific and precise shop and machine work, more exacting inspection, and are consequently worth far more to the owner, they are sold today for less per unit of value than any similar apparatus made. Greater skill, greater specialization, greater achievement do not make the "AMERICAN" cost more—they do make it worth more.

And the purchase price, low as it is, is greatly lessened in the after years of uninterrupted service because of low maintenance and operating costs. Your dollar has been creditably spent when it goes for "AMERICAN" apparatus.

Descriptive bulletins, engineering data and specialists' counsel are free for the asking.

**STARTRIGHT**  
WALKING SHOE

## The "Startright" Oxford

WE are taking this opportunity to present to the readers of The Nation's Health, the Startright Walking Shoe which is the best made orthopedic shoe on the market today. The Startright shoe really is an Orthopedic Shoe in Disguise, because it combines style and comfort and most women select Startrights for their appearance alone, forgetting the orthopedic qualities. Nothing but the highest grade materials and workmanship ever used in Baker shoes.

Startright shoes have been "approved" and are straight on the inside, have a flexible arch, plenty of swing to the toe to allow the proper movement and a low flat heel.

The Startright is our most popular model and is made over our 505 pattern.

Ask your dealer for Startrights and if he doesn't stock them—write us direct. Carried in stock in eleven styles.

SHOES FOR WOMEN

323-343 CLASSON AVE.

BROOKLYN, N. Y.

Orthopedic Shoes In Disguise

A residential center for students from foreign countries who are students at Columbia University is to be erected on Riverside Drive, New York, near Grant's Tomb. This is the gift of John D. Rockefeller, Jr.

One third of the 25,000 children in the kindergarten and primary grades in New York City who were found to be susceptible to diphtheria were immunized by toxinantitoxin last summer under the auspices of the health section of the New York County Chapter of the American Red Cross working with the Department of Health.

With the establishment of a special heart disease clinic at the Philadelphia General Hospital, work begun by fifty physicians last year has taken another step forward. Cardiac clinics were established during the past year at the Presbyterian, Pennsylvania, and Mount Sinai hospitals, while those at the University and Polyclinic hospitals are of recent date. It is expected that before 1923 twenty more such clinics will be established through the efforts of the Philadelphia Association for the Prevention and Relief of Heart Disease.

A bill has been introduced into the New York assembly which aims to control the sale, prescription and dispensing of drugs in New York City. The new measure requires that physicians must issue drug prescriptions in duplicate, one of which the apothecary is to file with local boards of health in cities of the first class, and in other parts of the state with the state department of health.

A physical examination for every citizen in the county is the plan of the Guilford (North Carolina) County Medical Society. Each physician in the county has agreed to serve at any time for as long a period as may be required. Drs. John T. J. Battle and William M. Jones of Greensboro, and Dr. William J. McAnnally of High Point are members of the main committee. Free clinics for rural districts and health lectures in schools and churches are also phases of the program.

The Wisconsin State Board of Health at its annual meeting at Madison elected the following officers: Dr. William F. Whyte, Madison, president; Dr. Edwin P. Hayes, Eau Claire, vice-president, and Dr. Cornelius A. Harper, Madison, state health officer.

A special section for the study of the problems of industrial safety, both in their national and international aspects, has been created in the International Labor Office, Geneva, in order to fulfil the objects of the International Labor Organization laid down by the Peace Treaty "to protect the worker against sickness, disease and injury arising out of his employment"; and to study the existing systems, practices and devices for eliminating human wastage and discover remediable deficiencies in those systems.

A chain of hospitals for crippled children will be established in the United States and Canada by the Shriners who gave their sanction to the project involving millions of dollars at the convention in Des Moines. Contracts have already been let for the building of hospitals at St. Louis, San Francisco, St. Paul, Shreveport, La., and Montreal. The hospitals will be under the direction of the best orthopedic surgeons available. They will be open to all children under the age of fifteen regardless of race or creed.

The General Conference of the International Labor Organization of the League of Nations in session at Geneva recommended that each member take steps to regulate the employment of children under the age of fourteen in agricultural undertakings during the night in such a way as to ensure to them a period of rest compatible with their physical necessities and consisting of not less than ten consecutive hours; that employment of children between the ages of fourteen and eighteen in agricultural undertakings be regulated so that they have not less than nine consecutive hours of rest.

Film lighting is less dangerous to the eyes of the motion picture actor than ten years ago, say various producers interviewed in the *New York Times*. While the lights are more powerful today than ten years ago, many small spotlights relieve the glare of the Kleiglits and the powerful Cooper-Hewett banks by diffusing the light. These streams of light from various angles neutralize the actinic rays which, if undiffused, are dangerous to the eyes because of their chemical properties. Rehearsals are usually conducted without lights and only for a short time during the actual filming of the scenes are the players' eyes exposed to the intense

light. On account of this diffused lighting, American motion picture actors run little risk of being blinded. The method of studio lighting now used in France was discarded in America ten years ago, producers assert.

The complete first-aid training course of the Bureau of Mines was recently given by Mine Safety Car No. 2 to a number of students of the Colorado Agricultural College at Fort Collins and the University of Colorado at Boulder. In Denver 150 city firemen were trained in first-aid. The crew of this car will give first-aid in the oil and lignite fields of Texas during the greater portion of the winter. City firemen in Dallas have recently taken the training.

The National Committee for Mental Hygiene has created a new division to be known as the Division on the Prevention of Delinquency, of which Dr. V. V. Anderson has been made director. An advisory committee has been appointed to assist the director in the development of the work. This undertaking is made possible by a special gift from the Commonwealth Fund.

A bill for the establishment of medical inspection of school children was reported favorably by the parliamentary committee on hygiene. The report states that except in a few large cities school medical inspection is practically unknown in France. It recommends the installation of a thorough system which shall give attention not only to the personal needs of the pupils but also to the sanitary conditions of the buildings, and urges the appointment of school nurses.

The Third International Labor Conference which met at Geneva adopted the following resolution regarding women engaged in agricultural pursuits: "That each member of the International Labor Organization take measures to insure to women wage-earners employed in agricultural undertakings protection before and after childbirth similar to that provided by the Draft Convention adopted by the International Labor Conference at Washington for women employed in industry and commerce, and that such measures should include the right to a period of absence from work before and after childbirth and to a grant of benefit during the said period, provided either out of public funds or by means of a system of insurance."

## The Storm Binder and Abdominal Supporter

PATENTED

A washable Abdominal Supporter adapted to the use of men, women and children for any purpose for which an abdominal supporter is needed. For General Support—as in Visceroptosis, etc. For Special Support—as in Hernia, Relaxed Sacro-Iliac Articulations, etc. For Post-Operative Support—as after operations upon the stomach, gall bladder, etc.

Children on entering Public School 64, New York City, are tested physically and psychologically to determine to which of the eight types of classes they shall be assigned. Specially gifted children enter "Terman classes," which besides having an enlarged curriculum, enable the child to finish the eight year course in six years; backward children are assigned to smaller classes, while pupils far below average and suspected of mental deficiency are put in separate classes. Provision is also made for neurotic children and for those whose physical weakness or emotional instability requires special handling. The enrollment of the school consists of 3,200 boys.

To care for the large number of epileptics in New York State, the New York State Board of Charities in its annual report renews its recommendation for an institution similar to the Craig Colony for the southern part of the state. A conservative estimate gives the number of epileptics in the state as 20,000. While many of these may never require institutional care the number who do cannot be cared for in the one institution.

Drs. George E. de Schweinitz, Philadelphia, Charles W. Richardson, Washington, D. C., and Fred B. Lund, Boston, have been appointed as the Committee on the Gorgas Memorial of the American Medical Association by President Hubert Work. This appointment was made in compliance with the request from the Gorgas Memorial Institute of Tropical and Preventive Medicine of Panama for the cooperation of the American Medical Association.

The National Safety Council is taking a census of all industrial physicians and surgeons, industrial nurses, and other persons engaged in industrial health work. This is the first attempt that has been made to enumerate the persons engaged in industrial health work. A registration form may be secured from the Na-

tional Safety Council, 168 North Michigan Avenue, Chicago.

The problem of adequately extending medical service to neglected rural districts was discussed at a meeting of the Massachusetts Committee on Rural Health and Medical Service. The Committee voted to continue its education of the laity as to the importance of improving medical service in the rural districts until such time as the Massachusetts Medical Society is prepared to undertake the improvement of this service.

Women's organizations in Montreal have under consideration a bill for mothers' pensions in the Province of Quebec which may be presented at the legislative session which opened on January 10. Over two years ago the Charity Organizations of Montreal started to maintain a number of widows with families as a practical test of the mothers' pension system, and this was continued up to the spring of this year, when the French, English and Jewish organizations undertook the care of the families of their own races, pending the passage of a mothers' pension law. It is thought that the proposed system will not be much more expensive for the city in the long run than the present plan, under which a large number of children are being cared for in institutions at the rate of \$9 to \$11 a month for each child. (*Labor Gazette*, Canada.)

A letter to the *New York Times* calls attention to the fact that revolving doors are a distinct menace in times of fire or other disaster. To throw back the doors flat on their frames requires two operations and it is difficult to find a time when they are entirely free from persons. They allow only a limited number to pass through and in times of panic the result will be a pile up and clogging of the doors. With office buildings sometimes containing 14,000 persons, it is imperative to have doors that will allow clearing as rapidly as possible. The preposterousness of re-

volving doors would be seen if one were to suggest that they be installed in movies or theatres. The writer believes them fire traps in disguise and that steps should be taken immediately to remedy the situation.

Almost a thousand employees of the Davis Coal and Coke Company in West Virginia were recently given mine-rescue and first-aid training by the crew of U. S. Bureau of Mines Car No. 8. In addition, 111 previously-trained employees took the training. Classes were trained at Dartmoor, Benbush, Pierce, Davis, Coketon, Thomas, Kempton and Henry. Every official of the company at the towns named now holds a Bureau of Mines certificate, and 65.5 per cent of the employees are first-aid men.

That modern leprosy, unless its victims have open sores, is not a menace to the community is the contention of Dr. Royal S. Copeland, Health Commissioner of New York City. There are ninety known lepers in New York City at large, though under the strict surveillance of the city health department. Modern leprosy can be acquired only through the blood and is not to be confused with the Biblical disease, says Dr. Copeland. Several of the lepers were present at a meeting of the health department recently at which Dr. William L. Somerset, chief diagnostician, talked on "leprosy."

A Bureau of Municipal Affairs which will act in an advisory capacity to counties, cities and towns in Vermont has been organized within the Department of Political Science of Norwich University, Northfield, Vermont. K. R. B. Flint, professor of Political Science, is Director of the Bureau.

Although familiarity greatly diminishes the sensitiveness to vibration and noise, yet both are unfavorable influences in the workshop, and it is very desirable to avoid them as far as possible.—Amar.

## The Human Factor in Business

The comparatively recent development of class consciousness in the labor group, accompanied by the rise of leaders and the increased power for bargaining, has greatly altered the attitude of the worker or industrial wage earner. The rising tide of their demands was stemmed somewhat in 1914 and the ensuing years by the cry of the naturalists, but as Mr. B. Seeborn Rowntree points out in his recent book, "The Human Factor in Business," since 1914 a profound change has taken place in the psychology of the workers. These men were called from their shops and benches to new tasks: they learned of actual conditions elsewhere; they exchanged ideas with men from the Dominions and America, and it is not strange that they now decline to return until certain minimum requirements are fulfilled.

The bickering over wage rates is but a phase of a general situation, the whole bases of industry are being challenged. Rowntree enumerates the following conditions which must be secured for the workers, no matter what the industrial structure may be:

- (1) Earnings sufficient to maintain a reasonable standard of comfort.
- (2) Reasonable hours of work.
- (3) Reasonable economic security during the whole working life and in old age.
- (4) Good working conditions.
- (5) A status for the workers suitable to men in a free country in the twentieth century.

Heretofore these conditions have not been secured under the capitalistic system and many demands are made for the overthrow of the present régime and the development of a new order, syndicalism, guild socialism, the nationalization of the means of production, the redistribution of wealth, etc. There are really as many, if not more, suggestions for improvement than there are buses, certainly many confused and confusing issues. The author holds here that through legislation or negotiation

among employers and employees, conditions may be made more stable and satisfactory.

The present book is largely a description of the way in which the directors of the Cocoa Works, York, England, have tried to solve the human problems in business administration as to wages, hours, economic security of the workers, working conditions, and joint control.

It is impossible and unnecessary to enumerate the details which describe the regulations of hours, wages, shop conditions, and administrative adjustments. These are all fundamentals with which we are reasonably familiar and which are of interest chiefly as showing the readjustments and plans in an individual shop. The matter of joint control in industry, on the other hand, is one with which our experience is more limited. We think of the great organization and power of trade unions which enter the industrial field usually "to remedy a grievance or to put right an injustice." Now, however, the worker feels that his opinion and desires should be given weight and consideration before industrial warfare is actually declared. This in England has been shown by the development of the Whitley Councils, now numbering over ninety in various trades and establishments.

Longmans, Green & Co., 1921.

## Epidemiology and Public Health

Dr. Victor C. Vaughan has compiled a text and reference book for physicians, medical students, and health workers entitled "Epidemiology and Public Health." For forty years or more Dr. Vaughan has been in the front ranks of those fighting communicable diseases both in civil and in military society. This book, the first volume of which, on respiratory infections, has just appeared, is an attempt to compile and organize the experience of "field, laboratory, library and lecture room." Valuable data concerning the history of epi-

demiology are made available to the populace, in many cases for the first time.

It is impossible here to go into great detail concerning the endless labor and careful judgment which a work of this sort entails. This first volume includes among the respiratory diseases the coryzas, pneumonias, measles, smallpox, chickenpox, diphtheria, etc., giving in each case a description of the disease, its history, prevalence, susceptibility, immunity, transmission, control and bacteriology. The inclusion of influenza, cerebrospinal meningitis, poliomyelitis and glanders is of peculiar contemporary interest.

In the second volume will be included the alimentary, percutaneous, venereal and local infections, while the third volume will be devoted exclusively to public health or the administration of those agencies by which disease may be reduced to a minimum. As Dr. Vaughan points out:

We are inclined to boast that the age of pestilence has passed, but, with a fair acquaintance with the history of epidemics, I dare say that the world has never before known a pestilence more widespread, more intensive and appalling in its progress, or more destructive to life, than the epidemic of influenza which apparently came into being and grew in violence as the World War passed through its final stages. It seemed that Nature gathered together all her strength and demonstrated to man how puny and insignificant he and his forces are, with all his murderous machinery, in the destruction of his fellows. We have not passed beyond the age of pestilence. Much has been done in man's struggle against disease, but greater things are to be done. There has been no armistice signed between men and disease. Influenza, pneumonia, cerebrospinal meningitis, poliomyelitis, and tuberculosis are still using weapons against which our defense is quite inadequate. They employ strategy in approach and attack which we do not fully understand. In this war against epidemic disease we must not permit the elation due to past victories to make us less careful and thorough in preparation for the battles of the future.

## Dr. Work, President of A. M. A., New Postmaster General

Dr. Hubert Work, president of the American Medical Association, succeeded Will H. Hays as Postmaster General, March 4, following the latter's resignation. Dr. Work was formerly First Assistant Postmaster General.

Dr. Work was graduated from the Medical School of the University of Pennsylvania in 1885, beginning his practice in Greeley, Colo. Later he moved to Pueblo where he became a specialist in mental and nervous diseases. He founded the Woodcroft Hospital for Mental and Nervous Diseases, of which he is director, in 1896. In 1911 he was elected President of the American Medico-Psychological Association.

In addition to professional activities, Dr. Work has been prominent in politics. He was delegate at large from Colorado to the Republican National Convention in 1908, Republican State Chairman from 1912 to 1914, and Republican nominee for United States Senator in 1916.

## Manual of Operative Surgery

Seven editions of John Fairbairn Binnie's Operative Surgery have met with a well deserved success. An eighth edition, just at hand, the reviewer feels speaks for itself as being the best book of its kind. The eighth edition is of the same size and form as its predecessors and has been brought up to date in every detail.

P. Blakiston's Son & Co., Philadelphia, 1921.

## Health Education and the Nutrition Class

The New York Bureau of Educational Experiments has published the experience with nutrition classes in the city schools in a book entitled

"Health Education and the Nutrition Class." Jean Lee Hunt is the author of the descriptive and educational sections, Buford J. Johnson, Ph.D., compiled the studies of height and weight and mental measurements, and Edith M. Lincoln, M.D., has made the report on the physical examinations.

Possibly no other one phase of health work has brought into clearer relief the essential problems of health education and the better appreciation of its scope and place in the general education program. The social background, the character of the school population, the school and home environment, the inauguration and development of a program first in the grammar and then in the primary grades with an increased growth in weight and height resulting, form the major portion of the book. Various interpretations and recommendations for a program of research and general education are deduced.

The children in the particular group studied were of a fairly homogeneous Jewish population removed from the worst slums but in a crowded and unsightly neighborhood. The children selected were first measured for height and weight, those found by the Burk-Boas height-weight age tables to be 7 per cent or more under weight being candidates for enrollment. Five classes were organized during the first year, groups from the seventh, sixth, and first grades; one from the open air classes, and one from the Terman or special classes. For purposes of comparison twenty fifth grade boys were selected and given a program of school feeding.

The nutrition class procedure had been developed by Dr. William R. P. Emerson of Boston with special reference to the standards of the older children. The younger children and their special problems were intro-

duced to insure individual adjustment to school life. Every child was given a careful stripped examination: defects of eyes, teeth, ear, nose and throat were so far as possible corrected. By visits to the homes cooperation was secured there. The average caloric intake was to be two thousand per day with an additional 250 to 300 calories for mid-morning and afternoon lunches. Undue physical action as a factor in producing over-fatigue, and the importance of personal hygiene were particularly emphasized.

E. P. Dutton & Co., New York, 1921.

## Confectioner's Raw Materials and Sources

A brief account of the sources of confectioner's raw materials, the methods of manufacture, the chemical constituents, the various adulterants, if any, the modes of detecting such impurities, the more important uses of the materials, and, in some instances, the quantities required for different purposes is to be found in a recent hand book by James Grant, an English food expert and chemical adviser.

The book brings together a type of material formerly available only in very scattered sources. Sufficient elementary chemical information is given to permit the use of the rest of the book intelligently by any one interested in the general field. Emphasis is placed on the importance of cleanliness, light and air, the storage of materials, the careful weighing and measuring of materials, prices, and above all on enthusiasm for the work itself.

Longmans, Green & Co., New York, 1921.

The secret of national health is to be found in the homes of the people.—

## Army Data on Psychologic Studies

A complete report of the history, methods and results of psychological examining in the United States Army has been recently published in the Memoirs of the National Academy of Sciences, Volume 15, 1921. The report is edited by Lieut. Col. Robert M. Yerkes, Chief of the Division of Psychology, as an official document for the Surgeon General of the Army. It consists of three parts bound in a single volume. Part I, presenting the official history of the development of the service and its activities during the war, is supplemented by reproductions of all of the printed materials devised and used in conducting psychological examinations. Part II includes a complete account of the preparation of methods, their characteristics, and their evaluations as practical procedures. In Part III the results of examining are summarized and fully evaluated.

The entire report may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C. It appears in quarto size under the title "Psychological Examining in the United States Army," and includes VI-890 pages.

## Medicine for Nurses

The scope of this book, by John Henderson, as stated in the preface, is "to give the nurse a wider knowledge of the course of disease, the main symptoms and treatment with the underlying principles which guide such treatment."

The book is well written, and has sufficient scientific explanation to make it very easily understood. A nurse requiring guidance and learning, but handicapped for time to spend in deeper research, would find this little volume of definite value, as she would obtain a very comprehensive understanding in a short time.

As compared with the textbooks now used in many schools, it lacks a little, in detailed scientific research, which difficulty, however, might be overcome when the study of it would be supplemented by the work of the lecturer. In view of the modern advancement of nursing education the more detailed scientific work seems to be advisable as the student then seems to have an opportunity to fix her mind more definitely on the subject at hand and do better work. The nurse as a technical assistant needs more thorough training.

Edwin Arnold, London, 1921.

## Ariston Gelatine Desserts

6 Pounds  
One or  
Assorted  
Flavors

You may have:

Vanilla, Orange, Lemon, Pineapple, Grape, Cherry, Coffee, Strawberry, Raspberry or Loganberry.

Or the plain powder, without flavor or color, at one cent less per pound.

The Flavors are pure fruit juices, made a part of the goods in the process of manufacture.

In preparing to serve, you have only to add water. The flavor is then always the same, of uniform strength.

Ariston Jelly Powders are Quality Foods—carefully made, of the very finest grade of pure gelatine.

Your test of the quality lies in the wholesome odor arising when hot water is poured upon Ariston powder. Make any comparison you choose, and be your own judge.

All Ariston Food Products

Carry our guarantee for their purity and wholesome qualities

## U. S. Government Health Activities

BY JAMES A. TOBEY, WASHINGTON REPRESENTATIVE, NATIONAL HEALTH COUNCIL

UNCLE SAM is greatly interested in public health, so much so, in fact, that in each of the ten Federal departments there are bureaus which conduct some type of health activity. In all, there are thirty-six divisions of the government which are concerned, directly or indirectly, with some phase of public health. Of course, with many of them, health is a side issue; it is of major interest in only a few instances. The most prominent health agency of the government is, obviously, the Public Health Service. For some incongruous reason, this bureau is in the Treasury Department. The Public Health Service receives the largest appropriation, \$10,587,780 for the fiscal year ending June 30, 1922, and has the largest personnel, nearly 23,000 in 1921, most of whom, however, were engaged in hospital services, of any of the bureaus interested in health. The seven divisions of this bureau include Scientific Research, Marine Hospitals and Relief, Domestic Quarantine, Foreign and Insular Quarantine, Personnel and Accounts, Sanitary Reports and Statistics, and Venereal Diseases. Besides the Public Health Service there are also in the Treasury Department the Bureau of Internal Revenue and the Customs Service. The former enforces the anti-narcotic and prohibition laws and the tax on child labor; the latter cooperates with the Department of Agriculture in enforcing the Food and Drugs Act and meat inspection laws.

Another important bureau engaged in health effort is the Children's Bu-

reau in the Department of Labor. The scope of this bureau has recently been greatly increased by the passage in Congress of the Act for the Promotion of the Hygiene and Welfare of Maternity and Infancy. Other bureaus in the Department of Labor are the Women's Bureau which considers the health of women in industry, the Bureau of Labor Statistics which studies industrial hygiene, and the Bureau of Immigration charged with the health of immigrants and the exclusion of diseased persons from the country. In this same connection, the Consular Service of the State Department issues bills of health to vessels clearing for United States ports from foreign lands.

### Coordinated Effort

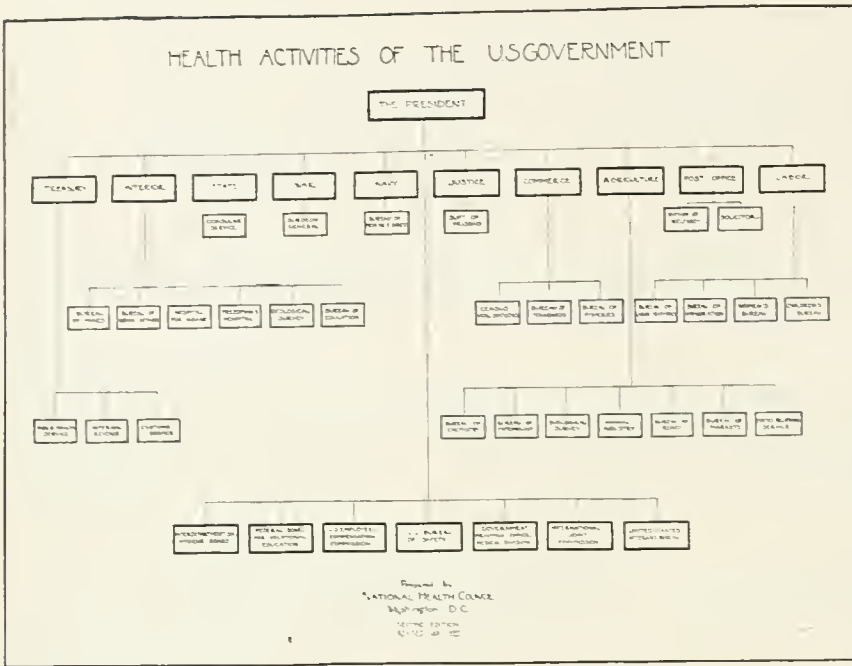

In the Department of Commerce is the Division of Vital Statistics of the Bureau of the Census which conducts the book-keeping of public health. Also in this department is the Bureau of Standards which has issued safety standards, and the Bureau of Fisheries which is responsible for the health of the people of the Pribiloff Islands. This bureau has likewise experimented with fish to assist in malaria control by eradication of mosquito larvae.

The Department of the Interior has several bureaus dealing with health. In the Bureau of Education is the Division of School Hygiene. The Bureau of Education also cares for the health of the natives of Alaska. The Bureau of Indian Affairs has a medical section and oversees the health of all the Indian

wards of the government. The Bureau of Mines does much accident prevention, safety and rescue work for miners, while the Geological Survey makes many studies on water supply of interest and value to the sanitary engineer. The Interior Department also controls the Government Hospital for the Insane (St. Elizabeth's) and the Freedmen's Hospital in the District of Columbia.

In the Department of Agriculture we find still more bureaus doing health work. There is the Bureau of Chemistry, conducting the analytical work under the Pure Food and Drugs Act, the Bureau of Animal Industry, coping with animal diseases, many of which affect man, and inspecting meat products in interstate commerce. The Bureau of Entomology studies insects influencing the health of man and the Bureau of Biological Survey, among other things, attempts to eradicate the rat and the plague-carrying ground squirrel. The Bureau of Roads has designed sanitary conveniences for farms and the Bureau of Markets inspects food products. Finally, the States Relations Service has, in the states, a corps of home demonstration agents who instruct persons in home economics, sanitation, health, and hygiene.

In order to complete the Cabinet departments, there may be mentioned the War and Navy Departments, each of which has a medical division, the Department of Justice, whose Superintendent of Prisons is responsible for the health of Federal prisoners and the Post Office Depart-

ment for injured government employes, the Interstate Commerce Commission has a Bureau of Safety, the International Joint Commission endeavors to prevent pollution of our boundary waters, and the Government Printing Office has a medical division.

All of these activities are shown graphically on the accompanying chart, which was prepared by the National Health Council. The Washington office of the Council, 411 Eighteenth Street, N. W., Washington, D. C., has also issued comprehensive reports on four of these bureaus, including the Division of Vital Statistics, the Children's Bureau, the Women's Bureau, and the Division of School Hygiene. While it may seem that there is much duplication in the government's health work, this duplication is more apparent than real. The public reached by the various agencies is generally different. Furthermore, there is so much to be done that it would seem that there is room for all these efforts. A certain amount of coordination is, however, essential. It is quite possible that the plans for Federal reorganization as developed by the Smoot-Reavis Committee may include a scheme for more close correlation between the health activities of the government.

ment, whose solicitor prosecutes fraudulent advertising of so-called health remedies through the mails, and the Director of Welfare who looks after the health of postal employes. Besides the departments under cabinet officers there are seven independent departments interested in some aspect of health conservation.

The Interdepartmental Social Hygiene Board works to diminish venereal diseases, the United States Veterans' Bureau cares for the mentally and physically disabled ex-soldier, the Federal Board for Vocational Education is engaged in rehabilitation, the Employees Compensation Commission provides medical and surgical treat-

## On Psychoanalysis and Such\*

THE present day interest in things psychological at first glance seems inexplicable. In an age so characterized by materialism it appears illogical to find popular interest in the mysteries of the mind as great as was current in the earlier days of religious credulity and metaphysical reason. It is not, however, as contradictory as it sounds, for despite rampant commercialism, Americans at least are as credulous as ever a people were, and as eager for new experiences in untried fields. Therefore when the call of the mysterious through this popularly styled revival of mind mystery took place, the whole people "fell" for it. The tangible hold offered by doctrines of mental healing swept off their feet sane parents who, even when they had allowed the diphtheria bacillus to kill their children, were not willing to admit that the matter of diphtheria toxin is more potent than the mind full of prayer!

It is the mind that counts—material existence and physical ailment are to be swept into the background. So the tabetics and the paralytics continue to limp home from Wednesday night meetings, their canes and their gaits beating a diagnostic tattoo on the pavement. But they are "cured," as they state with positive assurance. If we wonder why they think themselves cured while they still manifest such distinct symptoms as to make diagnosis a mere matter of inspection for a senior medical student we will arrive at the explanation of many of the confusing phenomena of modern medicine.

### Therapeutic Nihilism

No one wants to be sick, no one consciously becomes sick, no one imagines himself sick; yet physicians are well aware that fully half the work they are called upon to do is caused by, or at least directly influenced by the mental reaction of the individual patient. Even in organic lesions like heart disease, the symptoms shown by

the patient, the disease picture, depends to a great extent on the mental reaction of the patient. Charlatans and fakirs have long played upon the psychic phase of treatment, but physicians have been a little too slow in realizing the potent influence of the patient's mind.

The period of medical practice which was characterized by the use of very few drugs is known as the age of therapeutic nihilism, which means no treatment; but even therapeutic nihilism must be considered as a step in advance, for no treatment is certainly a marked improvement over the shotgun prescription which carried all drugs in the vague hope that some one of them would hit the bull's eye.

Very few diseases are cured by drugs; medicines at the best or worst are used only as first assistants to the great healer—nature. More recently the development of the science of bacteriology and the principles of immunity have added to the physician's store of remedies new and

\*The second of a series of articles on "Popular Medical Misconceptions," beginning with the March issue of THE NATION'S HEALTH.

specific vaccines, antitoxins, serums; and these have given new hope to treatment—hope of specific cures in given diseases by specific remedies. That in many instances this hope has not been realized does not in the least detract from the importance or value of the tremendous advances in knowledge which have been made possible by this new line of inquiry.

### Tangible Proofs of Service

While the age of therapeutic nihilism marked a great advance over previous periods of polypharmacy, and the more recent biological and chemical tendencies are certainly in the right direction, both periods are strangely lacking in attention to the mental makeup of the patient. Drugs were taken away, the old shelf was cleared, but nothing was put back in its place. And patients must have medicines—else what's a doctor for? The average patient is much more interested in getting something to cure his ills than in being told that his ills are such as not to require medicines. This was well illustrated in the case of a rather harassed, middle-aged man with chronic deforming arthritis, badly situated financially, who on the occasion of a visit to his physician's home, sought advice, mainly concerning the rehabilitation of his business status. At the close of the visit he asked the amount of the fee and, on being told that a fee for business advice was entirely unnecessary, he became indignant, opened his purse, and extracted a dollar bill which he insisted was the physician's just deserts. A few weeks later he was suffering from a severe attack of arthritis. The same physician attended him and left two prescriptions. The patient pulled his cash from under his pillow and extracted, this time, two dollars. Knowing the very impoverished condition of the patient, and appreciating the delicacy of his feelings, the physician remonstrated about taking what must have been a fair share of his total capital; but the patient insisted: "Well, Doc, I gave you a dollar the other night when you did not give me a prescription; certainly two prescriptions are worth two dollars." (This was before prohibition days).

It is well enough to say that medicines should be used only when necessary, and that patients should not be humored with placebos. A very sound doctrine that, but one showing a fundamental perversion of the idea of medical art. Deprived of all music and stage setting, the art of practice of medicine consists in getting pa-

tients well. Admit that correct diagnosis comes first of course, that nature does the work, anyhow, and no one can argue the question from an academic point of view. But, if you yourself or your children have ever been sick, your interest lies in getting well, and you want the doctor who in your opinion, will cure you. If you have unusual confidence in him, you will believe that medicines are not necessary, but on the side you are apt to take a dose of castor oil, anyhow. If your confidence is not one hundred per cent strong and Nature lags a bit, you want to have objective proof of your improvement. It is regrettable true that some patients shop from physician to physician, merely because they lack the common sense to realize that one good doctor is worth a dozen, good or bad, and they have not the confidence in medical science which is necessary to successful therapeutic effort. So they run the gamut, and at the end of a certain time one of two things happens: either they are well,—“cured” by physician number twenty-three,—or they are still sick, their minds are in a turmoil of doubt and perplexity, and they are “willing to try anything once.” They have tried legitimate medicine, and it failed to cure; next they go to Christian Science, or they are psychanalyzed, and read Freud, the latest and most popular lure to the intellectual.

### The Lure of the Intellectual

This explanation accounts, we believe, for a certain number of individuals who jump to *isms* and are so fascinated by the new thought as to forget their ills. It does not account for the large number of persons who flock to the “study” of new things as an intellectual pastime. Of the newer attractions for the intellectual, psychanalysis offers most. Why? First because we are living in a psychological age. What caused and what followed the destruction of civilization between 1914-1918 has caused many individuals to ponder over thoughts never before even suspected. O'Shaughnessy, V.C., came from the front with ideas which O'Shaughnessy Irish farmer never had. Then too, the war brought a taste for unheard of, new experiences, and the search for new experiences is always a psychological motive of prime importance. Add to all this, dissatisfaction with the unwillingness of the average physician to grasp the significance of mental reactions in disease—and, in our opinion, you have a formula for the present widespread interest in

psychanalysis and other psychological matters.

Many persons talk about psychanalysis and know not whereof they speak. They know something about repressions, about dream interpretations, about complexes; and they know also—indeed they do—that psychanalysis bases much on sex. They know that a fellow named Freud started the ball rolling, some are Freudians, some are Adlerians, and some are Jungians. (One might be facetious and talk of the female followers of Jung as Jungfraus). Much of the knowledge of most of the followers of psychanalysis is half-baked. The fundamentals of the Freudian philosophy are profound, the ramifications intricate, and it requires deep study of psychology to appreciate the relative value of the newer schools of thought. And if in general a little knowledge is a dangerous thing, a smattering of psychanalysis is like playing with poisonous gases, which, neither seen nor smelt, do untold damage before their presence is suspected.

Well, what are we going to do about it? The answer seems fairly clear. First recognize the widespread general interest in it and learn it well. Sift the good from the bad, the truth from the mystery in which it is veiled, and make it by our own efforts common property. Doctors should be ready to discuss the matter and should know enough to talk straight from the shoulder. They must also know enough of the methods of diagnostic psychology to be able to combat what is evil in present day practice of psychanalysis. The modern novels are filled with Freudian complexes, often unnecessarily complex.

### The Hidden Complex

The doctrine of mental or even physical ailments being due to a conflict in the subconscious mind, resulting from repression of some desire, is a fundamentally sound doctrine and can neither be laughed nor sneered away from the thought or practice of modern medicine. The Freudian thesis that practically all such conflicts are based on sex repressions is not generally accepted by thoughtful psychologists. Important though the rôle of sex may be in the production of nervous states, numerous other repressions come into play on an entirely different basis. The woman who subconsciously desires life in a big town with the glamor of the theaters, the opera, the libraries, but whom circumstances force into drudgery on a farm, is apt enough to de-

velop headaches, gastric distress, backaches, just exactly as the soldier in the trenches, finding life intolerable, developed the war neurosis, wrongly termed "shell shock." The unsuccessful business men whose income is less than his tastes and the demands of his family require, in time may become a nervous dyspeptic. The constant conflict between life as it is, and life as we would have it, does not always find expression in anarchistic explosions. Most of us are compelled to carry on as best we can, but the effort to effect a compromise may result in a neurosis or psychoneurosis. Sex may or may not be one of the elements in the conflict.

### The Mind and Body

When in such a state of psychoneurosis, a full expression of such troubles with a sympathetic listener is often the best cure, indeed, often the only cure. The psychoanalyst takes months, the doctor with a sense of psychological values may take only a single visit to discover the cause of the trouble, and usually the sensitive doctor can cure the condition rather quickly. We have recently seen a young woman with marked nausea and vomiting who was tremendously distressed by her week of illness. Only a half hour was taken to discover that the stomach symptoms were the result of some mental disturbance, and when at the end of the hour the young lady told of her interest in a man who apparently was not interested in her, the stomach disturbance disappeared—and remained absent. Though this was a case of man and woman, there was no sex element in it beyond the sex element in all wooings; there were no suppressed sex desires beyond the desire of the healthy female for marriage. The danger of psychoanalysis lies in introducing into such a case a sex element which vulgarizes the situation, and is completely unnecessary for a straightforward explanation.

Other "cases" might be cited to emphasize the point that in neurosis conflicts, our suppressed desire need bear no relation to sex or to the other man's wife! A woman had seen many "professors" for a group of symptoms referable to her stomach and intestines, and no two of the busy practitioners had agreed on diagnosis. She had been told she had gall-stones, ulcer of the stomach, that there was nothing the matter with her, and had finally been sent to the office of a young practitioner, whose assets were a good education

and plenty of time. Careful study showed no organic lesion. The condition was evidently the result of a serious shock to her nervous system which found expression in that most susceptible of all organs, the stomach.

A little plain detective work revealed to the young medical man that all the symptoms had followed the death of the patient's only child from diphtheria. Diphtheria deaths are not always necessary. The patient accused herself, the neurosis developed. She then became the object of sympathy, and her self-directed accusations were relegated to the background by the care and attention now lavished upon her, her pains and aches, which were bad enough, but not half as bad as the thoughts of her dead child. When the disturbing suppression was explained to her, and proper treatment instituted, she actually became well over night—and the mother of another healthy child within the year.

A word is necessary about dream analysis, the weird and unusual procedure of much in psychoanalysis. Dreams, occurring as they do in the interval between sleep and consciousness, represent the only memory of this state. Some individuals dream not at all, others dream vividly of things pleasant and unpleasant.

Dreams have a definite basis in past experience, usually a conscious though frequently forgotten experience, and not very infrequently they are the result of a definite disturbance in the body itself. In psychoanalysis dreams are interpreted usually on the basis of remote and far fetched causes, practically always on a sex basis. A woman, scared by newspaper headlines, dreams she is being pursued by a burglar, but the dream is held to be erotic and to carry significance far beyond the poor woman's own ideas. A young girl, no matter what her dreams may be, is, according to psychoanalytic interpretation, the victim of sex. We cannot help wondering how far such methods would go in interpreting the dreams in the case of a man who invariably experienced the most vivid and most disturbing nocturnal conflicts whenever he ate cheese, but whose dreams entirely disappeared after his chronically inflamed appendix was removed. The night period of relaxation often allows an expression of suppressed libido, but it takes a wide stretch of a most fertile imagination to refer all dreams to a sex basis, and in many instances such reference must be distinctly harmful.

The object of this plain spoken dis-

ussion is simple enough. "The truth will make you free" is the motto of a big American University; let us divest certain tendencies of modern thought of popular misconceptions. To do this we must be analytical and critical. Neither the medical nor the lay mind can afford to accept at face value all that is offered. Let us accept what is of proved value and reject the vague, the mysterious, the plainly dishonest, the dangerous; then, sooner or later, the misguided will see the light and legitimate therapy will be enabled to utilize all that is good.

### Army Camps Plan to Train This Summer

The War Department has under advisement the training of 227,000 men in military camps this summer, according to a special dispatch to the *New York Times*. Plans contingent on the appropriation by Congress provide that approximately 160,000 members of the National Guard, 30,000 reserve officers and specialists, 10,000 student members of the Reserve Officers' Training Corps, and 27,000 civilians will receive training.

The National Guard troops are to be trained in their own respective states, provided suitable Federal or state encampments are available. Camps of fifteen days' duration will be held for the National Guard States comprising each army corps area.

Most of the training for the 30,000 organized reserves, 10,000 student members of the Reserve Officers' Training Corps and the 27,000 civilians will be conducted at Fort Ethan Allen, Vt.; Camp Devens, Mass.; Plattsburg Barracks, N. Y.; Camp Dix, N. J.; Camp Meade, Md.; Camp Bragg, N. C.; Camp Benning, Ga.; Camp McClellan, Ala.; Camp Knox, Ky.; Camp Custer, Mich.; Camp Grant, Ill.; Fort Snelling, Minn.; Camp Funston, Kansas; Camp Travis, Texas; Fort Logan, Col.; Camp Lewis, Wash.; Presidio of San Francisco, and Presidio of Monterey, Cal. Other camps and stations of the regular army will be utilized to a lesser extent.

Applications for attendance at citizens' military training camps will be accepted at corps area headquarters after April 1. Arrangements are based on 3,000 of these citizens in the camps of each of the nine corps areas.

Camps for the Reserve Officers' Training Corps will be especially arranged to conduct the training required for the units of the several branches of the service.

# The Physician As An Instructor In Health\*

By Training and Contact the Doctor is by  
all Odds the Best Equipped Health Agent

BY SIR NAPIER BURNETT, K.B.E., M.D., CHIEF EXECUTIVE OFFICER, BRITISH RED CROSS SOCIETY, LONDON, ENG.

WIDESPREAD as is disease in its many forms throughout the world, there is something else that, fortunately, is even more general than disease, namely, health. Too long has health been interesting to individuals only when there has been a departure from the normal, as by the onset of some phase of disease. More recently health has come to be recognized as a distinct entity in itself, a positive state that can be preserved and maintained, not merely the antithesis of disease.

The general public today has just enough knowledge of personal hygiene to excite its interest and desire for more. People are more anxious to hold on to health than at any former time. Health notes in the daily and weekly press are eagerly read by great numbers. What is needed and what is being asked for in a measure is a fuller knowledge of the principles of physiology applied to the maintenance of personal health. Because of his knowledge and his right of entry into the homes of the people, the general practitioner of medicine is the individual best equipped of all the health agencies to render this service, representing as he does the one point of contact between scientific research and popular need.

Preventive medicine in the popular mind has long been interpreted as restricted in large measure to such matters as general sanitation, a pure water supply, efficient drainage, removal of public nuisances and the spread of infectious diseases, in other words, to the prevention of certain diseases as they affect the general community as a whole. This definition of public health as applied to the functions of the Sanitary committees in our system of local government has been largely responsible for retarding the progress of the prevention of disease in the individual man, woman, and child, which has been described as "the real focal point of the problem," namely, the application to the individual of the medical knowledge which we already possess for the preservation of health and the arrest of the beginnings of disease.

*Only by utilizing the general practitioner as a health agent can the public receive the health information it needs and desires. When it is realized that disease in its preventive stages rarely comes to the notice of health officers, the rôle of the doctor assumes great importance.*

*In order to further preventive medicine in Great Britain, the author urges that medical students become instructors in health as well as physicians in disease, that the Council of the British Medical Association inaugurate a constructive disease prevention policy, and that the medical profession assume the responsibility of maintaining the nation's health, not leaving it entirely in the hands of voluntary agencies and public health officials.*

Sir George Newman, Chief Medical Officer, Ministry of Health, in his Priestly Memorial Lecture, 1920, has lucidly outlined the outstanding features of a survey of the health conditions existing in this country. His deductions were based on data obtained from school medical inspection, national health insurance work, and the results obtained in the examination of recruits by the Ministry of National Service during the last two years of the war.

Speaking of this evidence, Newman says:

As a result of ten years of school medical inspection, we know that not less than a million children of school age are so physically or mentally retarded, defective, or diseased, as to be unable to derive reasonable benefit from the education which the State provides.

From the insurance returns for 1914-1916 we know that more than half the insured persons in England and Wales claim and receive medical treatment every year and that among these persons alone there was upwards of fourteen million weeks of reported sickness per annum. This is equal to a loss of working time amounting to 270,000 years per annum, all of it due to sickness and most of it due to preventable sickness.

These figures represent an enormous economic loss to the Nation, and since we know that much of this sickness and disease is preventable, it is important that the attention of the medical profession should be increasingly directed on a national effort towards the solution of the problem. The prevention of disease must no longer be regarded as the sole province of municipal medical officers, for there is much disease, especially in its earlier phases, that never comes within the knowledge of the official medical officer. In fact, from his official position, the medical officer's knowledge of the prevalence of disease is not obtained except in the form of the notification of infectious diseases, of disease in epidemic form, and by means of registration of diseases that have terminated fatally, and from information gathered by the health visitors. Of the great number of sick persons daily attended by the family physicians this official obviously can have no definite information. Therefore, it seems reasonable to suggest that if real progress is to be made in eradicating much of the preventable disease, a much larger section of the medical profession will have to become interested in this work than is the case today.

"The chief hindrance to the practice of prevention is lack of knowledge on the part of the public," says Newman in his lecture mentioned above. Briefly then, the position is that on the one hand we possess, as a result of scientific research, a large mass of accumulated knowledge in medicine and surgery, dealing with the nature and causation of disease, while on the other hand there are a great number of people who in their ignorance become the victims of avoidable disease.

Two illustrations will serve to show how important results were obtained in the prevention of disease. It is well known that in the South African War Great Britain lost more men from sickness than by bullet, whereas in the recent war sickness and disease were responsible for a much lower percentage of deaths than in any previous war. This favorable result was obtained in large measure by the ar-

\*Delivered as an address before the Glasgow University Medical Society.

rangements made by the Army Medical Service for the maintenance of health and the prevention of disease. Smallpox was prevented by vaccination; inoculation against typhoid fever produced amazing results; tetanus was prevented by the free use of serum.

Health was maintained by an adequate and carefully selected dietary; suitable clothing was supplied; efficient sanitary arrangements were provided; and a clean water supply was available. Bathing facilities, rest camps, regulated exercise, were all arranged with the one object of maintaining a high standard of health among the troops. In short, knowledge was available and made use of for the prevention of disease.

### Knowledge Prevents Disease

The second illustration of the effect of knowledge applied towards the prevention of disease refers to infant mortality. In 1900 in this country when there were practically no infant welfare centers or health visitors, the infant mortality rate was 154 per one thousand births in the first twelve months of life. In 1914, when the welfare centers, mostly voluntary, numbered 250, the infant mortality rate was 105. In 1919 the death rate fell to 89 per thousand, while the number of centers increased to 1,412. The lowest point yet recorded in infant mortality rates was in 1920, when the figure for the Country was 80 per one thousand births, and the welfare centers numbered approximately two thousand. There were other factors at work, of course, in producing this great saving of infant life, but it is generally admitted that the main factor was the valuable instruction in preventive medicine given at these welfare centers.

If such valuable results can be obtained in one section, much can be done in other directions by the adoption of similar ideas. Medical men are now and have for some time been engaged, in a small measure, in the practice of preventive medicine. This does not refer to the personal consultation by the individual seeking advice or to the important research work carried out in the hospital which gives us the knowledge of the nature of disease upon which the practice of preventive medicine is founded, but rather to the other aspect of prevention, namely, imparting instruction in first aid and home nursing, school medical inspection, and instruction given at welfare centers.

Who is to impart this requisite knowledge is the next question. In

America there is a large amount of literature in the form of leaflets and booklets being issued monthly to the general public from the offices of an ever increasing number of health agencies or societies, all dealing with some aspect of the prevention of disease and all seeking to instruct the individual in the matter of how to maintain health and avoid disease. Their great watchwords are "Health is Wealth" and "Health is purchasable." This health literature reaches me regularly, and from a perusal of it, I can come to no other conclusion than that it must in due course exercise a considerable influence on the prevention of disease.

Again, this popular health propaganda is not confined to voluntary agencies, but is also being taken up as a commercial proposition. One life insurance corporation was persuaded some years ago by one of the directors to employ some medical men to draw up a few leaflets setting out in popular language certain elementary facts about health and the prevention of disease. This form of instruction became so popular that today the company is the largest insurance corporation in the world, having more than sixteen million policyholders. But not only did the propaganda prove immensely popular, but it also proved, and continues to do so, the most financially sound investment the company ever made. The company now possesses a large staff of medical officers, fully trained nursing service, and medical statisticians.

The following quotation relates to their visiting nurse service: "The service today covers over ten million persons in the United States and Canada. In June, 1909, 730 visits were made to policyholders. In 1919, over one million visits were made."

Last year over £100,000 (\$500,000) was spent on providing a fully trained nursing service absolutely free to their policyholders.

### "Health Work Pays" Slogan

The following statement concludes this insurance society's annual report for 1920:

The outstanding fact in the record for 1920 is that *Health Work Pays*, whether conducted by governmental or by private bodies. It means longer and happier lives for the great mass of the population engaged in the world's work. The health experience of the year 1920 is but another confirmation of the wisdom of the policy of life insurance health conservation work. The low mortality record in 1920 means that 38,000 fewer deaths occurred among our industrial policyholders than if the health conditions

of 1911 had prevailed, and 13,000 fewer deaths than if the death rate of 1919 had occurred. Health work which brings such results is worth more than it costs, and this demonstration should encourage other agencies, both public and private, to extend their activities in the health field.

The third incident worthy of attention is a comparatively new movement taking place in a few of the medical schools in America. Men are graduating as Hygienic or Sanitary Engineers after taking a partial course in the curriculum of medicine with special study in the direction of prevention of disease. This is an unfortunate movement, and it is to be hoped will not take root in this country. Surely it is incumbent on anyone who seeks to practice the doctrine of preventive medicine to be equipped by a complete study of the full range of medicine in order that he may absorb the whole extent of available knowledge regarding the nature of disease. In short, he must know about disease before he is competent to preach its prevention.

Preventive medicine has been eloquently preached during recent years, but nearly always as something in the abstract. But until the great force hitherto little used in this direction, namely, the general practitioner of medicine, is made use of, we will fail to make the progress that we ought to make with preventive medicine in the concrete, for he, of all others, is the individual who enters into close relationship with people.

### Medicine Trains for Health

First of all, the training which a physician receives gives him adequate equipment as a teacher of health. The medical curriculum is of necessity divided into so many compartments or "years" of study. The first year of study, dealing with biology, physics and chemistry, subjects which the average students find so irksome, has the dual purpose of being in the first place disciplinary, that is, to instruct the mind in scientific method, and secondly to reveal important general principles applicable to the later studies.

The second year deals with anatomy, histology, and physiology,—structure and function of the normal,—in other words, with the foundations upon which is based the human machine for the maintenance of what we regard as health. The remaining three years are occupied in studying the *nature of disease* and its treatment. Such a course of study is intended to furnish the future medical practitioner with the requisite

knowledge for the diagnosis and treatment of curative medicine. This training likewise equips him for taking a lively interest in preventive medicine, for, as Newman has expressed it, "the foundations of preventive medicine are built upon a body of knowledge concerning the nature of disease."

In actual practice, the medical practitioner equipped with the requisite knowledge for dealing not only with "cure" but also with "prevention," in the main interprets his duties as lying along the line of the treatment of sick people,—that is, he waits for employment by people when they become his patients,—namely, people who have lost their hold on health. In other words, the doctor today relies on the apostolic injunction that "the 'whole' need not a physician but those who are sick." This doctrine in the light of modern knowledge requires a fresh interpretation, namely, the "whole" need the physician of health and the "sick" the physician of disease. From the nature of his training, the general practitioner of today embodies the dual capacity of being able to instruct his *clients* how they can retain their health as well as treat his *patients* who suffer from disease.

The subject of the doctor as a teacher of preventive medicine cannot be adequately discussed without reference to finance. Speaking generally, it will be admitted that the doctor derives his income from his "patients," those who consult him in their hour of sickness, at least such was the case until the advent of the National Health Insurance Act, and obviously his income fluctuated with the prevalence or absence of disease.

Before the insurance act came into force, the trend of both central and local legislation was to encroach upon the income of the practitioner by removing some of his patients and placing them in charge of the full time public health officials, and this tendency has been even more accentuated of recent years, so that today when the practitioner diagnoses his patient as suffering from any of the notifiable infectious diseases the patient is likely to be removed to the Infectious Diseases Hospital, and there be treated by the municipal doctor. Again, the School Medical Service now sanctions treatment of certain child ailments at the school clinics. Tuberculosis patients go to the Municipal Tuberculosis Dispensary or Sanatorium. Obstetric cases are now seeking admittance to the hospitals in increasing numbers.

I am not criticising this tendency

of recent legislation. All I desire to point out is that these are many incursions into what the practitioner hitherto regarded as his province and from which he derived part of his income. But with the coming of the insurance act, the practitioner's income has become more stabilized. He now derives a considerable proportion of his income on the basis of a per capita rate for the number of people on his panel list, with the result that he is paid at present by people who are well and also by those who consult him for disease.

Supposing a doctor has two thousand persons on his panel list. He may actually be consulted by and treat anywhere from eight to ten hundred of these, the remaining ten to twelve hundred who are well and for whom he also received payment, he never sees. In other words, he receives more of his income from "well" people than from the sick. Hence the comparatively low rate of the capita-tion grant. This is the basis of any insurance scheme.

#### Clients and Patients

It is not an insuperable difficulty to devise some scheme whereby the panel practitioner might receive one rate of remuneration for his services to his clients who are not ill and who desire to be instructed in matters pertaining to health, and another rate for the patients who consult him.

There are doubtless many families whose income excludes them from the benefits of the National Health Insurance Act but who would readily agree to pay a fixed sum per annum, as was formerly the custom in some parts of Scotland, to the family medical attendant to look after them both in health and in sickness,—in short, to be the health instructor to the family. This system now exists in Sweden, and the rate of remuneration is from £4 to £5 per family.

In conclusion, I appeal to three different authorities, first to medical students to consider the views briefly outlined and to seek to equip themselves with the knowledge that will enable them to become teachers of health as well as physicians for disease. Secondly, I would appeal to the Council of the British Medical Association to take up a constructive and forward policy in the matter of the prevention of disease.

The health of the Nation is primarily the concern of the medical profession, and preventive medicine in the fullest meaning of the term should not be left entirely to voluntary agencies and public health officials for it

deeply concerns the interest of the general practitioner as the agent who secures the closest contact with the individual man, woman, and child.

The wide field of Industrial Hygiene, for example, has scarcely been touched in this country and immense results might be secured through a forward policy inaugurated by the British Medical Association in a campaign for the attention of employers to the doctrine that the health of the worker means wealth, not only to the employees, but also to the employer. The inscription over the gates of one large factory in America is "Work here and live long," meaning that within the "works" are to be found the best possible hygienic conditions. Not only is an ambulance and first aid station established in the factory under the control of a resident nurse, but medical officers are retained by the firm to supervise the health conditions of the workers, and once a year each worker is medically examined, and thus the early signs of disease are detected and treated.

Thirdly, I would appeal to those in authority in medical schools for some opportunity to be given either just before or after the final examination in medicine whereby students could attend a short course of lectures on what might be called Social Medicine or Advanced Hygiene, in order that they, the future practitioners, might be the better equipped for their work as health instructors.

#### Mothers Receive Protection in France

In France the national budget for 1921 made appropriations or maternity and infant welfare subsidies to departments and communes taking measures to bring about an increase in the birth rate, it being the same amount as in 1920, 3,000,000 francs. Assistance is also given to women in confinement and to nursing mothers, with other appropriations connected with maternity and infant welfare. The total exceeds that of last year for the same period by 15,050,000 francs.

In an effort to further the development of juvenile court standards, the Children's Bureau, U. S. Department of Labor, is publishing a series of articles on the subject. A report just issued by the Bureau is that of Dr. William Healy, Director of the Judge Baker Foundation, Boston, who writes on "The Practical Value of Scientific Study of Juvenile Delinquents."

# Common Foot Troubles As Induced by Shoes

By RALPH B. BETTMAN, M.D., F.A.C.S., CHICAGO, ILL.

CIVILIZATION frequently forces the human body to adapt itself to usages detrimental to the functioning of its organs and members. Especially is this true in the case of the foot. From early childhood there is a continuous abuse of the foot. Sometimes it is the abnormal function that produces the noxious results, in other cases the shoes. The city dweller treads continually on hard, unyielding surfaces. Whether this be street, sidewalk, or floors, the ground walked upon takes up none of the jar. While naturally constructed to diminish shocks under conditions of modern life the foot is put to great additional work. The detrimental effect of hard pavements is generally recognized, and no good horseman will allow his horse to gallop or trot on cement or asphalt. We have learned to soften the foot-fall by wearing rubber heels, which protect the foot and thereby abolish much foot strain. Certain industrial positions require individuals to remain standing over periods of many hours. Standing is a continuous muscle strain and therefore more fatiguing than walking, which may require more actual muscle work, but which is intermittent.

Sometimes because of economic conditions people are forced to be on their feet when they are ill and ought to be in bed. In illness the ligaments or muscles of the foot are much less apt to stand the strain. Industrial physicians and military surgeons need to bear this in mind. Both see cases where, because of certain economizing or other reasons, individuals who are in a weakened condition are compelled to work and stand many hours. The

result often is a yielding of the structures that hold up the arch in the foot. This leads to a "weak foot" which, unless carefully and sensibly treated, results in a "flat foot" with its concomitant symptoms.

## Contributing Conditions

Poorly fitting socks and stockings and webbed shoe linings cause much discomfort and augment foot trouble. The "socks of sister Sue" were of serious import on the march, as many a doughboy will recall. The shaggy external appearance of our "trench boot" may have caused some slight annoyance when trying to "doll up" to impress "a jolie mademoiselle," but

X-ray of same foot wearing a high-heeled slipper. Note the distortion of weight distribution. The heel here carries very little of the load, while the front of the foot (the transverse arch) must bear the brunt of the burden.

the smooth unlined inner surfaces made the thirty and forty kilometre hikes possible.

Rubber overshoes, because of their impermeability, interfere with the natural evaporation from the skin of the foot and, if worn too long, react upon the sweat glands.

We now come to the ills produced by the shoe itself. Many of the ills are due to the poor fit of a well constructed shoe, many to the construction of the shoe itself. Of all the enemies of the foot, the czar, Style, stands out preeminently. In order to be in style the average person, otherwise intelligent, will gladly bear the pain of illfitting pointed shoes. We ridicule the Chinese custom of binding women's feet, but inconsistently tolerate styles that are almost as unnatural and injurious. A narrow foot, small in size, is the desideratum. To accomplish this a normal foot will be pushed and squeezed into a last several sizes too small.

Many shoes are constructed wrongly from heel to toe and from sole to upper. The leather may be too impermeable. A certain amount of air should reach the skin of the foot. Rubber shoes cause higher sensitiveness from an increased perspiration. Patent leather shoes, also, if worn too steadily, make the feet ache. A heel helps the walker to lift his weight in making a step. A high heel however, instead of helping, greatly increases the work of the foot. In the first place a high heel throws the shock of the weight from the rear of the foot, where it belongs, to the point of the foot, where it does not belong. The heel of the human foot is composed of a large heavy bone covered by a cushion of fat and it is so constructed in order to break the blow of the step. However, in a high heeled shoe, the ball of the foot bears the brunt of the step.

In the second place, high heels instead of having a broad tread surface have a very small one, so that the weight is thrown on the wrong part of the foot. The foot instead of being solidly and firmly on the ground is wobbly and unstable, which means that the muscles which hold the foot must work many times as hard to keep the ankle from turning at every step.

Another ill in our modern shoe in many instances may lurk in the "shank" or instep of the shoe. Some firms advertise a flexible shank, others a rigid shank. The main essential in either case is not to have the shank so wide that the inner side of the instep receives no support below to counterbalance the downward pressure from the lacings above.

The longitudinal arch. The inner and outer longitudinal arches are sketched into this x-ray photograph of a normal foot. Note the flattened external arch, which bears the weight, and the high internal arch, which gives the foot its elasticity. This picture was taken with the foot tilted slightly out of a direct lateral position.

X-ray of normal foot, showing direction of weight distribution. Note the more direct line from the ankle joint to the heel, demonstrating that the heel is the chief weight-bearing point.

The front part of the shoe may be mechanically at fault in several ways. Usually the shoe is long enough so that the toes do not press against the tip at every step. Style has decreed for

Showing the comparative outlines of shoes conforming to the normal outlines of the foot and the hampering requirements of a dress slipper.

a pointed shoe. In order to adapt itself to the average pointed shoe the natural shape of the foot must be altered. The little toe is pressed toward the midline; the big toe, instead of being parallel with the foot, is also bent towards the midline. Normally all five toes point straight ahead. In the shoe the little toe is deflected medialwards, the fourth toe slightly, the middle and the second toe may point straight ahead, while the big toe is again turned medialwards.

The foot in a natural gait points almost straight ahead, like medium step or something like a moderate pigeon toe. This is not considered elegant; "out-toeing" is supposed to be more graceful. To produce this the shoe is flared or turned so that the out-toeing effect is brought about. Another harmful influence is the purposeful twist in the last so that the foot is slightly rotated, lifting the outer margin upwards and allowing the arch to drop a very small amount. This is done by manufacturers so as to prevent the shoe from "running over" on its outer border. In this way the weight is thrown from the outer margin of the foot, where it naturally belongs, to the inner margin of the foot.

A shoe may possess one or all of these defects. These errors in construction for the most part are taken care of by the intrinsic medium of the foot. However, to do this the foot must be continually adapting itself to unnatural conditions. Sooner or later some condition such as fatigue and a twist of the ankle may be superadded to the burden the foot

already bears and an unpleasant train of weeks is precipitated. It is now in order to discuss a few of the sequela of poor shoes.

### Common Foot Troubles

**Corns.**—The little toe, being small, weak, and unprotected, is the first part of the foot to suffer in the endeavor to force a "D" foot into an "A" last. The pressure is not constant, but is augmented by stepping on, and diminished by lifting the foot, resulting in a rubbing motion as well as pressure. Luckily, the skin reacts to the stimulation, and instead of being worn off and causing an ulcer, forms its own protection. This protection or callus increases in size and, extending downward deeper into the skin, brings about the exquisitely agonizing condition known as a corn. Remove the cause for the corns and the corns themselves will disappear

The imprint of a normal foot.

with a speed and sureness equal to the claims of any "corn cure" ads. Renew the cause, and the corns very shortly will also re-appear.

However, the corn does more than just ache and instigate profanity and homicidal tendencies in crowded street cars and elevateds. Each step is painful. Therefore, at each step the voluntary or involuntary effort made to tread on a part of the foot which will not increase the pressure and friction against the corn involves an abnormal use of the foot, increased stress, and eventually, pathologic changes.

**Bunions.**—A somewhat similar proceeding occurs on the opposite side of the foot, that is, the big toe side. The big toe is crowded over medialward. The phalange-metatarsal joint becomes more prominent. Friction over this joint causes irritation over the metatarsal head. There are, of course, underlying factors which bring about bunion formation such as

congenital enlargements of the head of the first metatarsal, congenital deflection, sesamoid bones, etc. There is no doubt, however, that the tendency to this condition is augmented by im-

Third degree flat foot. In a condition like this the bony symmetry of the foot is destroyed. Pains and aches and many ills are in its train.

proper shoes, and it must be realized that the shoe, at least as far as symptoms are concerned, is a factor of the greatest importance. When a bunion has once formed, the deformity persists. A broad shoe, a shoe which will not crowd the big toe, which will hold the heel and instep firmly and place no pressure upon the head of the first metatarsal will in most instances give relief from symptoms. In mild cases this will be sufficient and no further treatment is required. In other cases operation is called for, but after such an operation the patient should be advised especially regarding shoes. Here again, as in the case of the corn, due to pain and deformity, abnormal function leads to greater abnormality of anatomy and function.

**Calluses.**—Any increased strain on the longitudinal arch will likewise cause an increased strain on the metatarsal arch (the transverse arch). Also, as we have mentioned, the high heel is a factor directly causing undue weightbearing of the transverse arch. The result of an increased amount of work of the transverse arch is that the arch gradually collapses and the head of the metatarsals, especially the third, instead of being directly weight supporting toward the end of the step only, that is, while the entire weight is being rocked from the outer side of the foot to the inner side, is directly weight bearing the whole time. A malformation of the longitudinal arch with the increased strain may bring about the same condition. The elasticity of the transverse arch is diminished and the head of the metatarsal strike

the ground with an unnatural jar. The result is callus formation, especially under the head of the third toe, pain in this region, and a condition called metatarsalgia. In a great number of cases not only the callus but also the pain will disappear with appropriate strengthening of the main or longitudinal arch of the foot.

### Weak Foot and Flat Foot

How do shoes affect the longitudinal arch? Or better, what rôle do shoes play in the development of "weak foot?" The term "weak foot" is preferable to "flatfoot" because the foot which causes the greatest amount of discomfort is not a flat foot, it is a foot which will become flat eventually but which still has a normal appearing arch. However, the supports of the arch are weak; after a certain amount of strain the arch does flatten but speedily returns to its normal shape when rested. A bona fide flat foot gives comparatively little trouble. In order to understand what a weak foot is and how it is caused, a knowledge of the mechanism and function of the foot is necessary.

In the normal foot, the weight is transmitted through the bones of the leg to a bone called the talus which forms a hinge. Through the talus the main weight is borne by the broad heel bone called the calcaneum. The weight of the rest of the body is borne by the forward part of the foot, but to a very much less extent. The arch of the foot is composed of the smaller bones. The outside of the arch is comparatively flat. The inner border of the arch on the contrary is high. When weight is placed on the foot the outside of the arch rests practically its entire length on the ground, the inner side of the arch however, is preserved. The arch has most aptly been compared to a series of springs, the outer spring being flat and rigid and the inner curved.

A cross section of the ball of the foot reveals another arch, the transverse arch, which also can be compared to a spring of slight curvature. What happens when a step is taken is that the heel of the foot hits the ground first. The fat pad over the calcaneum takes up most of the jar. When the entire foot lies on the ground the weight is supported mainly by the heel, but also by the springs which form the arch. The outer spring flattens so that the entire outer side of the foot rests on the ground. The inner spring also flattens slightly, thus giving resiliency to the foot, but the inner part of the instep does not

touch the ground. The foot is thus balanced on the arch, just as the chassis of an automobile is balanced on its springs. As the step continues the powerful muscles of the calf pull the heel up and the weight is placed on the ball of the foot through the transverse arch. Here again the spring action of the transverse arch gives a resiliency to the step. The first push of the step is made by the big toe.

The framework of these springs is made up of the bone of the foot, held together by the ligaments and muscles. Any weakening or stretching of these ligaments and muscles will weaken the springiness of the foot.

It is hard to understand why out-toeing should popularly be considered elegant. The shoes are flared so as to bring about the desired gait at the expense of poise, grace and nervous force.

Fatigue brings about such a weakening and allows a consequent stretching. Any abnormal gait causes fatigue. In a few minutes an unnatural gait harms the foot more than hours of an easy normal walk. Any of the abnormal conditions already discussed—corns, bunions, calluses, brought about by webbed linings, etc., cause a voluntary or involuntary effort to spare the part of the foot. This means an abnormal gait, speedy fatigue, and a consequent injury to the supporting mechanism of the arches. For example, a walk which throws the weight on the inner side of the foot forces this part to do an undue amount of work. The weight, instead of resting on the ground, will have to be held up by the muscles and ligaments which form the high inner arch. It is at once apparent that this calls for a great amount of extra strain. It is just as if we tried to rest by forming a bridge with our head and heels instead of lying flat. The arch naturally stretches under this strain and causes the symptoms of flat foot. It

is impossible for the foot to function well if any part of it is impaired. There applies here the fable of Aesop in which the various organs of the body claimed that the stomach was doing none of the work, but was getting all the food, but in the strike that followed the organism as a whole suffered.

### Remove Cause is Remedy

If recognized early enough the great majority of weak feet can be remedied by removing the cause of the abnormal action. Weak feet can be prevented by preventing abnormal mechanical action. Arch supports may have a place in the treatment of weak feet, but only a very minor place. The normal arch needs no support. A tired arch does. For this reason it is often wise to counsel shop girls, clerks, motormen, and other workers who are on their feet a great deal, not to wear bedroom slippers or tennis slippers after a strenuous day's work. A tennis slipper or bedroom slipper gives no support to the arch. Or it may be wise to advise that if they do want to change to slippers when they get home, to wear some sort of an arch support at these times. A well fitting and well constructed shoe will not only prevent the conditions described, but will in the majority of cases cure them. As long as undue pressure or friction is brought to bear on the little toe, a corn will form in spite of any or all so called remedies. Only when the transverse arch is relieved of the abnormal strain, whatever the cause may be, will the metatarsalgia disappear. The symptoms of a bunion in most instances are relieved by removing the noxious conditions which, together with the anatomical features, definitely cause the symptoms. A weak foot is cured by readjusting the weight bearing, by removing the actions which have weakened the supporting muscles and ligaments. A well constructed and well fitting shoe should hold the foot snugly, should not press unduly on any one place. The heel and arch should be firmly held. The front part of the foot should be free to expand as the weight is shifted. The heel should be broad, giving a large and stable tread surface. A rubber heel is an advantage because it takes up a certain amount of the jar. The shank should not be so wide that it offers no counteraction to the downward push of the lacings. The leather itself should not be entirely impervious to air.

# Education Measures Against Venereal Diseases\*

## A Plan Really to Instruct, Naturally and Logically, and Without Psychic Stress

BY KARL MARCUS, CHIEF PHYSICIAN AT THE HOSPITAL ST. GÖRAN, STOCKHOLM, SWEDEN

THE work of information and instruction respecting venereal diseases hitherto carried on in Sweden has been almost exclusively of a private nature. On some few occasions, lectures have been given for the adult population, and in a few secondary schools, girls' schools especially, sexual hygiene has been dealt with in detail, the instruction, in some cases, embracing infectious venereal diseases, too. Some school doctors attached to secondary schools for boys have, on their own initiative, lectured on the subject to the youths at a period immediately before they sit for their matriculation examination.

Better care has been taken of the military in this respect, as in the instruction in general hygiene that the military surgeons have to give the men, there have long been included a couple of lectures on venereal diseases at present supplemented by information on the more important regulations of the Venereal Diseases Act of 1918, and on the obligation lying on the men to avail themselves of medical prophylaxis.

But when the state seriously took up the struggle against venereal diseases, it saw more than well the extraordinary importance of a thoroughly carried out system of instruction and information in this matter. There was included in the Act, consequently, a special regulation whereby the state authorities undertook the arrangement of such work, section 27 stating:

The Government will issue regulations respecting the measures necessary for spreading among the population a knowledge of the nature and dangerously infectious character of venereal diseases, of the means available for the prevention of the conveyance of infection, and of the obligation attached to each one who is attacked by such a disease of obtaining medical aid as soon as possible.

In consequence of this legal regulation there was appointed in October, 1918, a Royal Commission empowered to draw up a plan for public instruction and education respecting venereal diseases. The Commission consisted of a representative for primary

schools, another for secondary schools, one for the Committee for Popular Instruction, together with a woman doctor and a man doctor. After a thorough investigation of the question, the Commission sent in its report of 232 pages in March, 1921. The very radical proposals made by the Commission as a result of its labors will certainly encounter serious opposition, and it is by no means certain that the authorities in whose hands rest the power of deciding in the matter—the Government and the Parliament—will adopt the Commission's views. As, however, the investigation made appears to have been an extremely thorough one, the evidence adduced convincing, and the proposals made extremely worthy of attention, I shall give herewith—as a reply to the questions now brought forward,—a short reference of the report in question.

### The Basis of Investigation

(1) First of all, there was sent to various educational establishments in Sweden a question form, asking for information as to whether instruction in sexual hygiene and venereal diseases was given in the school in question. By the answers received it was seen that only an extremely small number of the educational institutes communicated with, gave such instruction. Most of the textbooks in zoology do not say a word as to the propagation of the human race or of the organs of propagation. It was mostly in the secondary schools for girls and in the state training colleges for elementary school teachers that this subject was dealt with. In secondary schools for boys the subject was touched upon in, at most, one-fourth of the whole number of schools applied to.

By the kind offices of the Swedish Foreign Office, the Committee also placed itself in communication with various other civilized countries and received replies, displaying more or less interest in the matter, from most of the countries applied to. The reports received were, as a rule, of a negative nature. Any thorough work in the way of information and instruction respecting venereal diseases

hardly seems to occur in any of the countries in question, although much had been done voluntarily for the enlightenment of the public, especially in Germany and, during the last few years, in the United States of America, too.

The Commission, therefore, had been unable to build on any great experience, either in Sweden or in other countries, when it began its task. The first thing it had to do, then, was to investigate the necessity of "sexual instruction," as the Commission has called it. In this matter the Commission received powerful support from the above-mentioned replies to the inquiries sent to the various educational establishments in Sweden. Most of the headmasters or mistresses pointed out the extreme desirability of such instruction, not only for the youth of both sexes at a suitable age, but also for the general public. As the general opinion in many civilized countries is, that enlightenment on sexual questions is one of the most powerful weapons in the struggle against venereal diseases, and as prominent representatives of the Swedish educational corps had certified to the great desirability of the introduction of such instruction, the Commission felt that it was able to assume the position that there really existed the necessary starting point for its action, viz.: the demand for the instruction of the youth and adults of the population with regard to venereal diseases and their great danger for the individual and the community at large.

Even before the appointment of the Commission, various authorities had expressed their opinion on the subject. For example, the Royal Commission for Venereal Diseases in 1910 had expressed the desirability, aye, the necessity, of instruction in schools and for the adult population in respect to sexual questions. The Central Board of Education, the Government Board of Health and the Municipal Board of Health of Stockholm had all expressed their opinion of this report and had, in the main, supported the views brought forward there. At a meeting of teachers in 1906 the question formed part of the

\*Read before the Northern European Red Cross Conference for Combating Venereal Disease, Copenhagen, May 20-25, 1921.

program, and the introducer of the discussion emphasized most strongly the necessity of sexual instruction in schools. A Royal Commission for the re-organization of national education expressed more doubt on this point, however. In its reports of 1912 and 1914 it has stated that it was desirable, but scarcely possible, to carry out such instruction in the schools. In opposition to this, a meeting of teachers at the above mentioned State Training Colleges pointed out most emphatically the utility and necessity of instruction in sexual hygiene. The Commission—the one mentioned at the beginning of this paper—enjoyed the support of various authorities, therefore, when it expressed its opinion as to the need and absolute necessity of such instruction.

### Two Directions of Effort

(2) The Commission divides its work into two separate sections: instruction in schools, and instruction outside the schools for the adult population. As regards the first part of the problem, it is pointed out that so-called sexual hygiene and instruction respecting venereal diseases are so intimately connected that they ought not to be made separate subjects of instruction, but should form one branch, entitled by the Commission, "Sexual instruction." This instruction should be available to all youth, at the age of about fifteen, in the form of an abbreviated course. If this age is fixed, then every child attending school would receive sexual education as, at present, the obligatory school instruction embraces children of the ages of fifteen and sixteen. That part of the youth after this age who remain in secondary schools until the matriculation examination between eighteen and nineteen years of age would, in addition, immediately before sitting for this examination, receive a somewhat more extended course of instruction in the subject. Sexual instruction in the schools should be based on the instruction in biology, and especially the instruction in hygiene which forms part of the course in biology, should consist partly of purely biological details and, in addition, of social and ethical considerations. The shorter course should embrace about two hours; the longer one, three to four hours. The latter course should include a somewhat more detailed account of the social points of view in the matter. First and foremost, the instruction should be given in connection with biology, but also, in suitable parts, in com-

bination with instruction in Christian doctrine, sociology, and psychology. The teaching should preferably be given by a medical man or woman; but, when no doctor can be had for the purpose, by the ordinary teacher. In addition, the boys should be taught by themselves and the girls by themselves, preferably by teachers of the same sex as the pupils.

Respecting the subject matter of the course as planned, the Commission pointed out: "That the aim of the said instruction, concerning venereal disease in regard to suitability and natural sequence, should be: (a) To impart a knowledge of the nature and dangerously infectious character of the said diseases; (b) To point out the import of these diseases as regards the individual, the family and the community at large, both for the moment and in the future; (c) To arouse attention and reflection in regard to the danger of infection; (d) To point out that the danger of infection can be avoided and counteracted, and the means of doing so; (e) To instil the obligation attached to each one who is, or who fears he is, attacked by such a disease, to seek medical help at once; and (f) To create in every one a vital feeling of responsibility in respect to the health of himself and others, and to the welfare of society in the respects just mentioned."

In this connection it should be emphasized that the said instruction should not, of course, aim at giving any knowledge as to the diagnosing of these diseases, nor of their treatment, so that the greater number of the symptoms of disease and of the method of treatment need only be mentioned to the degree necessary to attain the aims above mentioned, or so as to make the instruction sufficiently clear. It is self-evident that all instruction in sexual matters must be so carefully chosen and given that it will not excite the passions or the imagination, nor unnecessarily frighten and disturb the pupils.

The pupils, at the age when it is intended this instruction is to be given, will already have acquired the necessary preparatory knowledge by their earlier study of botany and zoölogy, in addition to which, they have been made familiar with the course of fecundation and fertilization in plants and animals, and have also gained some knowledge of the development of the fetus within and outside of the mother, in different classes of animals. The so-called minimum course, therefore, should embrace the following outline:

The essentials of fecundation: the ovum and semen cells, their character as conveyors of heredity, their coalescence. The sexual glands and other organs of generation,—these not to be described in detail, but merely in outline together with their functional importance. The main features of the development of the fetus, its connection with and dependence on the mother's body. The character of the process of birth. The continued dependence of the newborn child on the mother.

It should be pointed out that the organs of reproduction are not capable of carrying out their functions before the body has attained a certain development. Menstruation and pollutions are mentioned as signs that show that the sexual organs have begun to attain maturity.

It should further be instilled that the natural aim and end of sexual life is the propagation of life, and that this should not take place before the individual has reached full development and has become capable of forming a home, and of caring for and educating the children; it should also be emphasized that until this happens, sexual continence should be observed.

The dangers of onanism (self-pollution) should not be unnecessarily emphasized or enlarged on, as this may lead to nervous derangements. The temptation to onanism felt by many young persons can best be avoided by directing the thoughts to other subjects by means of suitable employment, proper reading, bodily exercise, and a hygienic mode of life in general, together with an avoidance of loose conversation and provocative reading.

It should be emphasized that the external sexual organs, like the body in general, should be kept clean. The instruction for girls should teach the importance of menstruation-hygiene and of the observance of the greatest possible cleanliness in childbirth.

### Venereal Diseases

(a) *Their extension.*—When giving instruction respecting venereal diseases, a short account should be added of their great extension and of the social danger they consequently form.

(b) *Symptoms and course.*—The symptoms and course of these diseases are described as briefly as possible.

*Syphilis.*—The disease is a bacterial one which begins with a sore, whence the virus makes its way into the lymph and thus in a short time, is spread throughout the system. The course of the disease varies very

much, being sometimes slight and sometimes exceedingly malignant; shorter or longer periods of apparent health can intervene between outbreaks of the sickness. Syphilis often causes infectious sores and eruptions of various kinds on the skin and mucous membranes. It can attack internal organs and, *inter alia*, occasion heart complaints, paralyses, blindness, deafness, mental diseases, and death. The disease can be transmitted to the sufferer's children.

*Gonorrhoea* (the "clap").—The disease is caused by bacteria which attack the mucous membranes, as a rule, those of the sexual organs, and also the conjunctival membrane of the eye, especially in newborn children. Its course is attended with a greater or lesser discharge of pus from the parts attacked, accompanied, as a rule, by aching and pains. It can give rise to inflammations in and around the sexual organs and, especially in women, can cause lingering and great suffering. Gonorrhoea can lead to sterility in both sexes. If the eyes are attacked, blindness can follow. The disease can also spread to the joints and can cause very acute inflammations of the joints.

*Soft Chancre* (*ulcus molle*).—This disease is caused by bacteria which attack the skin and mucous membranes, usually those of the sexual organs and the surrounding parts. The disease appears in the form of sores which are often attended by swellings of the glands.

In regard to the diseases mentioned, it is to be pointed out that medical science has now discovered methods for their treatment which, in ordinary cases, lead to the restoration of health. The earlier the doctor's aid is sought, the greater are the chances for the invalid to obtain a speedy and complete cure. Warnings should be given against applying to quacks, and against self-treatment.

(c) *The danger of infection and its avoidance*.—Venereal diseases are usually spread by sexual intercourse, but also by other bodily contact, and also indirectly by infected objects. Every one who is accustomed to have occasional illicit sexual intercourse should be suspected as a carrier of contagion. Even persons who "look perfectly healthy" may be carriers of infection. The absence of outward, visible signs, consequently, is no guarantee that the individual in question is free from infection. One should avoid coming into intimate contact with persons who may be suspected

of being carriers of infection. The greatest cleanliness must always be observed with regard to closets, the table service, towels, etc. The very usual circumstance that not only acquaintances but also strangers are in the habit of kissing little children, in season and out of season, always constitutes a danger of the possibility of the conveyance of infection to the children.

Sexual continence is the best preventive against infection. Such continence is not dangerous to health. Assertions to the contrary have no foundation in fact. Training to self-control is a necessity. Caution should be observed with regard to the consumption of alcoholic liquors, as such drink not infrequently acts as a stimulant to sexual emotions and also deprives one to a greater or less degree of self-control.

(d) *Measures in case of suspected infection*.—If there exists merely the suspicion of having come into contact with a part of a body attacked by infection, or with an object tainted with infectious matter, one should endeavor to remove the virus by very careful washing and suitable means of disinfection, and, above all, one should go to a doctor at the earliest possible moment. Care should be taken, however, not to fall a victim to exaggerated and misdirected apprehensions.

(e) *Personal responsibility. The law*.—The pupils should be taught to perceive that each one must feel a sense of responsibility with regard to the health, care, and education of the race; that parentage should be held in respect by all, both man and woman, and that everyone is bound to preserve his health for the sake of a future family, too. It is each one's duty, therefore, to avoid exposing oneself, from thoughtlessness or wantonness, to the risk of being infected by venereal disease.

Everyone who is attacked by a venereal disease is bound by the law to submit himself to medical treatment. The one who knows, or who has reason to suspect that he is infected, commits a criminal and, therefore, a legally punishable act, if he exposes another person to infection. It would be possible to exterminate sexual diseases if everyone did his duty in the respects mentioned. Everyone should render his assistance in this matter. It should also be instilled into the pupils' minds that one has no right to condemn other persons because one may know them to be, or to have been, attacked by an venereal disease; neither has one

any right to raise unnecessary obstacles in the path of these persons with regard to their work, dwellings, and the like. If necessary, affected persons should be admonished and assisted in a tactful way to apply for and follow medical advice. It is to be remarked that the teacher employed should very evidently be allowed a certain freedom respecting the details of sexual instruction.

### A Comprehensive Course

The detailed course intended for the youth of more mature years should embrace, in addition to the matter for the minimum course, a somewhat more thorough and a deeper knowledge of the subject. In giving this advanced course the teacher should first remind the pupils of what they had previously learned in biology respecting the structure and functions of the organs of reproduction. Should, for any reason, such preliminary instruction not have been given to the pupils, these chapters should first be gone through. In connection with the treatment of the question of the structure of the ovum and semen cells, there should be mentioned the most important results obtained by research in the field of hereditary transmission, together with characteristics inherent or acquired. In addition, mention should be made of the importance for the body of the sexual glands as organs of internal secretion.

After this, a somewhat detailed description is given of venereal diseases and their various forms, this, when possible, with the assistance of object material; this latter, however, should only refer to the bacteria of the diseases and should not illustrate their symptoms. In this connection, the teacher should touch on the incubation period of the diseases, and mention should be made of blood tests for syphilis, and the importance of this method.

In this course of instruction, more time should be devoted to the social points of view than can be spared during the minimum course. To begin with, the extension of venereal diseases should be illustrated by means of suitably chosen statistics. Prostitution, too, should be briefly mentioned. The dangers to public health created by venereal diseases should be pointed out. There should further be emphasized the fact that these diseases, in consequence of their great frequency, play an important rôle in national economic respects, from the loss of time caused by the conditions

of the sickness. In addition to this factor, come the increased expenses resulting from the care, both of those affected and of those attacked by sequela. Many cases of insanity, idiocy, deaf-mutism, and blindness are caused by venereal diseases, and demand expensive care. Mention the existence of such special institutes as Welander Homes for children who are inherently syphilitic.

It should also be pointed out that, in consequence of the ravages of venereal diseases, the public health becomes deteriorated to a serious degree; that venereal diseases contribute essentially to diminish the birth-rate and that, in the opinion of many experts, syphilis can play a rôle as a degenerative factor.

During the instruction, an account should be given of the legal enactments now in force in respect to measures against the spread of venereal diseases, *i.e.*, the law of June 20, 1918, respecting measures against the spread of venereal diseases; the penal law Chap. 14, sections 21 and 45, and Chap. 18, section 11, as well as the law concerning the contraction of marriage and the dissolution of the same, Chap 2, section 6.

At the close of the course, there should be distributed to all the pupils leaflets on the subject, in which mention is also made of the above legal regulations.

The Commission emphasizes the importance of physical education—gymnastics, athletics, outdoor life—as an auxiliary in sexual education.

It would carry me too far to enlarge here on the Commission's detailed plan for sexual instruction in the various classes of schools existing in Sweden, but I cannot omit quoting the words of the Commission on the suitability of the doctor as a teacher in this subject.

### The Doctor as a Teacher

We should like to point out, first of all, that, of course, the preferable plan must be to employ a doctor—man or woman—to give the whole of the instruction in hygiene and, consequently, in sexual hygiene too. In the first place, a doctor possesses a greater knowledge of the subject and, in addition, the authority of the doctor is, as a rule, so great that it will be able to check the inclination that may exist among the pupils to receive the instruction in an improper or offensive manner. It is, however, only in a few cases that it will be possible to get a doctor to give such instruction. As a rule, though, for the reasons just stated, it is desirable that the instruction in sexual hygiene, at least, should be imparted by a doctor.

The fact must not be disregarded

however, that there exist circumstances which, in certain instances, make the doctor less suitable for the instruction now in question than the non-medically trained teacher. It is to be remembered that not every doctor can be presupposed as possessing the pedagogic tact and insight which must of course often be called for, when giving such instruction as that now in question and, in addition, the doctor, as opposed to the teacher, does not enjoy that great advantage given by an exact acquaintance with the preparatory knowledge possessed by the pupils, and other theoretical preliminary conditions, necessary, if the pupils are to be able rightly to utilize the instruction, and by a similar acquaintance with each pupil's individual bent of mind, all of which makes the teacher better suited to adapt himself to conditions which, in these respects, may vary extremely in the same class. Furthermore, it will be easier for a teacher to impart instruction in a clearer way, while many a doctor will be hampered by certain modes of expression due to his own technical training. Finally, it forms a strong point for the teacher that he is able to combine directly sexual instruction with other school subjects, while in this respect the doctor will have to adjust his occasional instruction with the school time-table, without any direct connection with previous or with subsequent lessons.

(3) When the Commission subsequently passes on to discuss the details of the plan of instruction, emphasis is laid, first and foremost, on the great rôle played by the home in this respect. The child's earliest questions on sexual matters, regarding "where it came from," etc., should not be answered evasively, with an order to keep quiet, or with absolute fables; the "stork" myth should be banished from the child's education. In the earlier stages of the instruction in the school, the subject is mentioned when, in the course of the lessons in biology, hygiene is dealt with. Both in the instruction in biology and in zoölogy, as well as in hygiene pure and simple, the problems connected with propagation should, gradually and clear sightedly, be so treated as to form a preparatory course in sexual instruction whereby, in a fully natural and consistent manner, the sexual instruction proper, which begins at the age of fifteen, is brought into connection with the above-mentioned subjects.

### The Part of the Public

There exists in Sweden a very comprehensive and well carried out organization, in enjoyment of partial State assistance, for the giving of popular lectures. The Commission conceives that this organization might include sexual instruction in its pro-

gram, a thought which, as a matter of fact, has already become a reality, although on a small scale. In these lectures, which ought to embrace a total of at least three hours' instruction, the more detailed school course should be the minimum dealt with. In such lectures, of course, more delicate matters can be touched on than those dealt with in school instruction, the age of the public making possible a better understanding of the ethical and social points of view of the problem. In connection with the lectures leaflets and pamphlets should be distributed. The idea is, that such lectures should be given exclusively by doctors. The expenses attendant on them should be borne partly by the State and in part be covered by a small fee for admission. I shall say nothing respecting the organization and the detailed plan of this instruction by means of public lectures.

(4) Even if, as was pointed out above, doctors can, to a certain extent, be reckoned with as responsible teachers of sexual instruction in the schools (*i.e.*, the secondary and the primary schools) in the towns, and also for such instruction there outside the schools, this is, of course, not the case in the extensive rural districts and in extremely small centers of population. If, in such places, sexual instruction is to be given to school children, resort must be had to the teaching staff available there, and this forms the most vulnerable point in the organization. At first sight, the difficulties appear so discouraging that one is tempted to ask if they are not so great as to form an insuperable obstacle to the entire plan of instruction. But on a closer investigation, however, one comes to the conviction that it will, probably, be possible to overcome the difficulties in question, even if a considerable time must elapse before the intended aim is attained.

Teachers in elementary schools are educated at state training colleges. In the time-table adopted for these educational institutions, one subject is a fairly detailed course in general and sexual hygiene. The Commission proposes that this course should be lengthened somewhat, by the addition of the subject, venereal diseases. The instruction in this instance should, preferably, be given by the college doctor, who in many places is actually the teacher in this subject. As regards the instruction in sexual hygiene of the future teachers, therefore, it would probably be a very easy matter to communicate so much

knowledge as would be requisite to enable them, in their turn, to teach the children the minimum course. A short handbook on the subject would probably be of the greatest help to these future teachers, and, at the request of the Commission, I have compiled one.

As regards the teachers in biology, again, who in *secondary* schools, may be delegated to give sexual instruction, it should be pointed out that, during the pursuit of their studies at the University and private High Schools, they even now have to take a very detailed course in general hygiene. (According to a list of subjects of study at Uppsala University, this covers no less than thirty hours). There would probably be no difficulty in adding the subjects of sexual hygiene and venereal diseases to this course, and one could, with equal certainty, depend on having specially trained doctors as the teachers in the subjects. The handbook just mentioned would, I imagine, be of great help in the future to these teachers in secondary schools too.

It is during the transitional stage—the period before a teaching corps, trained to give instruction in sexual hygiene, has got well to work—that the difficulties will be greatest. The Commission considers, however, that the teachers now at work could acquire the knowledge required for giving the most necessary points of sexual instruction, by means of special courses at their respective colleges or university (partly with State support) and by private study of the above-mentioned little handbook, etc., or, maybe, by consultation with some suitable doctor. The lectures which, during the last few years, have been given, experimentally, for teachers in primary schools, have shown that the necessary preliminary knowledge, and an appreciation, of the subject prevails among them, so that the interest shown in these lectures has been extremely great.

5. Finally, the Commission proposes that all textbooks in biology should be supplemented by information respecting sexual hygiene and venereal diseases; that suitable textbooks for the future teachers of the subject should be compiled, and that popular papers and leaflets should be written, which should be examined and approved of by the public authorities. Three specimens of such leaflets accompany the Commission's Report.

\* \* \*

During the course of its labors, the Commission has not been blind to the

many difficulties lying in the way of the proposed great work of enlightenment. That part of the work which concerns adults, offers the least difficulty in this respect. The public in Sweden is probably, at present, so unprejudiced and shows such an interest in the acquirement of a knowledge of sexual hygiene and venereal diseases, that it will be an easy matter to overcome the preconceptions that may possibly still exist on the subject. The new law which for several years has been the subject of public discussion, not only among doctors and other persons interested in the matter, but also in the newspapers, has paved the way in this respect.

The greatest difficulties arise, however, when we come to the question of the enlightenment of youth. The conditions necessary if the proposed school instruction is to be of any utility are, of course, (1) that a sufficient number of competent teachers can be procured, and (2) that the instruction is communicated in such a tactful and delicate way that no harm will ensue from it instead of the intended good. The Commission believes, however, that if the instructions and hints given in the report are followed, and if the sexual instruction is combined, naturally and logically, with the teaching in biology and, if it is also

given in connection with instruction in ethics and sociology, then the intended effect will be attained without exposing the psychic life of the children to too great a stress. This will, more especially, be the case if the influence of the *home* paves the way, so to say, for the future sexual instruction later on in the school.

### Alabama Malaria Control Planned

The chief matter under discussion at the recent meeting of the County Health Officers of Alabama was the new plan of doing malarial control work through the county health officers, on a country-wide basis. Announcement was made of a plan of cooperation between the State Board of Health and the State Board of Education, for school sanitation, and the establishment of courses in hygiene in the schools.

A new maternity ward for tuberculous patients has been opened in the Hospital Vicente Lopez y Planes, Argentina, according to the *Bulletin of the Pan American Union*. The ward has 32 beds and all the improvements and equipment of a modern hospital. This is the first ward of its kind in Argentina.

## Sanitary Control of Camps

THE direct sanitary supervision of beaches and bathing places in the summer is often hampered by the lack of rulings on essential features having to do with their control. These problems are springing up everywhere throughout the country and for this reason we print herewith a copy of proposed additional regulations for the supervision of beaches in and around New York City, drawn up by Dr. Louis I. Harris, Director of the Bureau of Preventable Diseases, in association with Mr. James D. Sullivan, the Counsel of the Department of Health of the City of New York.

RESOLVED, that the regulations of the Department of Health of the City of New York governing the conduct and maintenance of summer camps, and relating to Section 217 of the Sanitary Code, be amended by adding thereto a new Regulation to be known as Regulation 11 as follows:

All agencies in the City of New York which send children out of town on vacations of periods of more than one day shall be subject to the following provisions:

(a) Every agency conducting or

maintaining vacation camps shall be registered with the Department of Health of the City of New York, and shall have a certificate from said Department of Health.

(b) All such camps wherever maintained or situated shall be under the supervision and direction of the Department of Health of the City of New York.

(c) There shall be medical supervision in every camp.

(d) All children shall be examined by a physician immediately prior to departure for camp, so that all possible cases of contagious disease shall be excluded.

(e) No child of a family in which contagious disease exists shall be sent away to such camp, the agency taking all possible precautions to secure information.

(f) All facts relating to every case of communicable disease or suspected communicable disease at vacation camps shall be immediately reported in writing to the Department of Health of the City of New York.

(g) No person shall be employed or permitted to work in a vacation camp unless he shall submit to a physical examination, and to a Widal test and stool specimen examination, and shall have procured a certificate of health from the Department of Health.

# Increased Mortality Past Middle Age\*

## Periodic Medical Examinations Will Increase Average Longevity

By M. T. McCARTY, M.D., MEDICAL DIRECTOR, PEOPLES LIFE INSURANCE COMPANY, FRANKFORT, IND.

IT IS generally conceded that mortality up to middle life has decreased and that the average age of man at death has gradually increased, due to better hygienic conditions and better treatment and control of communicable diseases. It is now proposed to show that past middle life there has been a gradual increase of mortality, to discover the causes of this condition and propose a remedy. To prove the first point we must rely on available statistics, regretting very much that the United States life tables for 1920 have not yet been printed and that the latest available statistics are ten years old. The higher mortality for the ages past middle life is in striking contrast to the decreased mortality at the younger ages for both sexes during the past four decades. The following table shows death rates at all ages for 1900 and 1911, a study of which shows a decrease before middle life and an increase past middle life:

COMPARISON OF MORTALITY BY AGE GROUPS

Death Rate Per 1,000 Population.  
(Registration States as constituted in 1900.)

Age	Males		
	1900	1911	Inc. or Dec. %
Under 5	54.2	39.8	-26.57
5 to 9	4.7	3.4	-27.66
10 to 14	2.9	2.4	-17.24
15 to 19	4.9	3.7	-24.49
20 to 24	7.0	5.3	-24.29
25 to 34	8.3	6.7	-19.28
35 to 44	10.8	10.4	3.70
45 to 54	15.8	16.1	1.90
55 to 64	28.9	30.9	6.92
65 to 74	59.6	61.6	3.36
75 and over	146.1	147.4	.89
All ages	17.6	15.8	-10.23

Further study of such tables as are available seems to point in the same direction. In the comparison of the United States life tables registration area of 1910 and the American Experience table an increased mortality is shown. The New York table bears similar conclusions. It would therefore appear that the available statistics support the conclusion that the rate of mortality is increasing past a more or less clearly defined stage of life, called middle age. It now remains to disclose the causes contributing to such a result and find and apply

how these conditions affect insurance.

The figures of average longevity and mean expectation of life just quoted only emphasize the prevalent understanding that increased hygienic measures and sanitary knowledge, principally accomplished by public health authorities, are largely responsible for the result. The lessening and better control of infectious and communicable diseases and a reduced death rate in infancy and childhood are the factors which produced the beneficial results. The saving in mortality at younger ages is offset largely by the increased waste in the older ages. As a great amount of insurance is written on lives in middle age and later, when the desire and ability to pay for larger amounts become more noticeable, it is of importance to see where the losses of life arise and how they may be minimized.

### Degenerative Disease Toll

Past middle life the vital organs, especially the cardiovascular and renal systems, are subject to more rapid degeneration. This has always been characteristic of advanced ages. Such degenerative diseases claim 58.7 per cent of total mortality after age forty-five. To be more specific in the causes of death, according to the government and health statistics, heart and arterial diseases from ages thirty to thirty-nine increased 6.3 per cent; from forty to forty-nine, 19.8 per cent; fifty to fifty-nine, 30 per cent; sixty to sixty-nine, 56.3 per cent; seventy to seventy-nine, 156.8 per cent. Apoplexy decreased under age fifty, but increased from fifty to fifty-nine, 18.8 per cent; sixty to sixty-nine, 33.3 per cent; seventy to seventy-nine, 46.7 per cent. Kidney diseases decreased at all ages under forty, but increased from forty to forty-nine, 1.8 per cent; fifty to fifty-nine, 22.2 per cent; sixty to sixty-nine, 43.0 per cent; seventy to seventy-nine, 64.1 per cent.

About 30 per cent of accepted life insurance risks, supposed to be practically normal, succumb to cardiovascular diseases. Cancer has been gradually increasing as a cause of death at the rate of 2 per cent per annum. Of all deaths from this

cause, 90 per cent are over forty years of age. Possibility of control of cancer and other degenerative diseases is much more hopeful than seemed likely even five years ago.

The consumption of tobacco has risen from three billion cigarettes ten years ago to twelve billions in 1918, to forty billions in 1920, to fifty billions this year. Last year we spent two billion dollars for tobacco alone, or one and one-half times the cost of running our government. Women now smoke on a much larger scale than they used to. It follows, therefore, that if allowed to continue as they are doing, there will be a large increase in the patients suffering from cancer of the tongue, high blood pressure, and heart affections. This fact must be considered as somewhat explaining part of the cause of this increase. Detracting some from the accuracy of this is the constantly changing of the character of our population by adding to our population millions of Poles, Slavs and Italians which we did not have at an earlier date. But this does not, in my judgment, explain the increased mortality rate in the group past middle age, nor the fact that native born Americans today do not show an increased mortality past middle age.

The degenerative diseases have increased, but this report is somewhat offset by the fact that there are better and improved technical methods of diagnosis, and consequently more accurate reports on diseases than formerly. The result of this constant effort is to get more specific reports on the cause of death, but this will not explain altogether the increased mortality after the crucial age of man. The marked decrease in mortality which characterizes the earlier ages does not continue past middle age, but here is the line where this gradual decrease ends and the gradual increase begins, accompanied by such a class of degenerative diseases as has been referred to as caused by overeating and bad habits of life and lack of exercise, which bring on degenerative processes. Possibly a cause is increasing wealth and indulgence, along with intestinal toxins.

The American business man works

\*Read before the twelfth annual meeting of the Medical Section of the American Life Convention at French Lick Springs, Ind., March 1-3, 1922.

too strenuously and in far too many instances dies young, literally working himself into an early grave, and, too, on the other hand, the man who retires and idles his time away dies young also, just as idle machinery rusts out much quicker through non-use. So a happy medium of neither too much work nor too much idleness is imperative for a long life, but reasonable work is essential to health.

Our modern system of industry, factory system, and concentration subjects the people in cities to a more strenuous life, where the wear and tear on the system is greater and the results show a higher mortality past middle life. The fierce competition and strife for business supremacy sets a rapid and strenuous pace in the business and social life of today which we did not formerly have. Opportunity to live in the open close to nature and to get exercise and preserve the health is not today the simple matter that it formerly was.

### Bad Habits of Modern Life

All this goes to confirm the belief that there has been a deterioration, a decline in the vitality of the average person past middle age. The greatest factor that excites our apprehension is cardiovascular diseases, which play the preponderant part in the production of degenerative diseases. Hence poisons, irritants, such as heavy meat eating, overeating, auto-intoxication, improper elimination, red pepper, mustard, tobacco and alcohol are causes of the chronic irritation of the inside coats of the arteries and capillaries, followed by inflammations, swelling, thickening, hardening, narrowing of the lumen of these vessels, thus impeding the circulation and producing high blood pressure, enlargement of the heart and a degenerative condition of the tissues of the arteries and kidneys, resulting in apoplexy and premature death. Excitement, worry, and overwork cause an expenditure of nerve force along with the struggle for wealth and social position, playing an important part in causing these degenerative symptoms. This is especially noticed in the strain and stress of the fierce competition in our large cities.

Then we have the big dinners, late suppers and late dances or theater, heavy smoking, overeating, drinking, and other bad habits of life, and little rest, with application to business the next day, which results in degenerative processes. Think of the tired, overworked stomach, heart and kidneys—a tension with no vacation, no mercy to these overworked organs!

We should know that an excessive protein diet results in poisonous by-products which are absorbed into the blood as poison, such as meats and alkaloids of tea, coffee and cocoa, which act as irritants to the inner walls of the blood vessels and which lead to thickening, hardening and high blood pressure. Overeating has the mechanical effect of increasing the blood pressure and leading to arterial troubles.

There are about two million people in the United States who are seriously impaired from heart disease, and about one hundred and fifty thousand die each year from this cause, and virtually nothing has been done against this disease. Insurance statistics show that about 2 per cent of persons examined by insurance companies are rejected each year because of various organic heart troubles. We know that the presence of heart trouble greatly shortens the longevity of those afflicted. In insured lives in the industrial population the incidence of this disease is second to tuberculosis.

The death rate from heart trouble increases with age. The medical inspection of school children will result in a better mortality from this disease. Heart disease stands first in the list of causes of death in old age.

There has not been the progress in the control of the diseases of adult life that has been accomplished in the diseases of the earlier years through the prevention of acute infectious diseases. The former may in part be attributed to indifference to right habits of living and methods of prolonging life. I urge more scientific study of these degenerative diseases as to the best methods for their prevention and control. We undoubtedly have the proof of better medical and surgical procedure, better sanitation, and better hygiene.

Our bodies are reaping at middle age and past what has been sown in earlier years. The degenerative diseases are so often the sequela of diseases that have occurred in earlier life, impairments resulting from acute infectious diseases. Very often these impairments go unnoticed until past middle life, when the vitality has begun to weaken under the strain of years of activity, when they terminate into some degenerative disease. Therefore, more attention should be placed upon the prevention of the earlier acute infections to avoid these sequela and their resultant mortality past middle age.

Our vocation in life has much to do with our longevity. Those callings that wear out life very rapidly are

those that require drudgery and work in dark places. I believe that part of this increased mortality is due to a failure on the part of the people to adapt themselves to the changed mode of life since the introduction of so many modern conveniences. There is the modern automobile, the elevator, the telephone, free mail delivery, and numerous labor-saving devices which have reduced physical exercises that were formerly conducive to health and long life. The centralization of the people in the cities away from the country life has taken them away from outdoor air occupations and exercises for indoor air and sedentary pursuits. Many of these cases are the result of occupational hazards during early life. The prevention of mouth infections and bacterial diseases will lessen these degenerative changes in later years.

### General Neglect of Health

We can recall many cases involving breakdown heart and kidneys which are so frequent in those past middle life. So many of these patients are almost entirely ignorant of the methods of right living, devoting their whole attention to business affairs, to the neglect of the things which are of far more importance. They remain ignorant of the consequences of the inordinate appetite and their overweight and lack of hygienic exercise. There are many who pay a yearly fee to the lawyer for guidance to avoid litigation in business affairs, but the idea never comes to them to seek the advice of a competent physician to avoid the snares and pitfalls of physical infirmities, which are worse than lawsuits.

If we figure the relative economic importance of conservation of health and life of younger as compared with older ages, I believe that the economic value of life conservation past middle age is practically as great as it is for the younger ages. And here I do not want to be understood as in any way minimizing its value in control of communicable diseases of early life, but in considering the potential value past middle life there must be added the cost and value of experience gained and the cost of the great productiveness at these ages in contrast to that of the younger ages.

Early diagnosis is of the greatest importance in these degenerative diseases, and just as important is early treatment. With this in view, several life insurance companies now offer to the policyholders free medical examinations at frequent intervals, which has been found profitable to them.

The movement to urge those past middle life to be examined physically at intervals of one year at least, in order to discover incipient impairments when they might be cured, whereas if permitted to run on would go rapidly into the incurable class, followed by a breakdown deserves the earnest support of all life insurance companies, for we have evidence already of splendid returns where it has been tried. Too much importance has been laid on the sacredness of private property and too little on the duty of all to contribute to the welfare of the whole people. Preventive medicine has proved that it is an important factor in keeping off disease and early mortality. If the facts of this are ever gathered in the most thorough way, every citizen must be enlightened so that he will submit himself to a thorough examination once every year or oftener. The benefits of this to life insurance companies are self-evident, because early recognition in most diseases reveals their early stages when they are amenable to treatment. The early recognition of cancer, tuberculosis, Bright's disease, heart disease, diabetes, etc., together with the elimination of acute infectious diseases would add fifteen years to the average life, besides saving untold suffering and financial loss.

It seems to me that several companies doing business in a section could go together, share the expenses and offer free medical examination to the policyholders, and in this way find the first signs of degenerative diseases and then modify the mode of life so that the disease would be checked or modified. Today our modern life is making great and increasing demands upon the energies and vitality of people in the fierce struggle for success in life.

The efficiency of our nation depends upon the efficiency of the people that compose it, for mental and physical efficiency depend upon good health. To maintain our place in the world and to meet the keen competition of other nations we must be healthy, vigorous people. It is our duty not only to maintain our health standard at par, but to do what lies in our power on behalf of the health of our fellow men.

Such organizations as the Life Extension Institute of New York City and National Health Guard, which have for their object the rebuilding of American vitality to prolong healthful, useful years of life and make them more livable, and the conserving of human life and human use-

fulness, should receive our commendation.

We now have medical inspection of school children, whereby they are informed of their physical defects and encouraged to have them removed. This tends to prevent heart and kidney impairments later in life. If we had the same inspection in our shops and factories, and persons suffering from physical defects could be informed of the fact and advised to secure proper treatment or change of work where the nature of the work tends to aggravate the condition, this would be a most effective means of life conservation.

Insurance companies should encourage everything in the way of public education concerning personal hygiene, as this will result in avoiding losses brought on through neglect of the symptoms leading to serious and incurable diseases later on.

Dr. Fisher points out that the causes of death which predominate in higher-age groups are preventable to a degree that, if the diseases and conditions involved were controlled to the extent of the facilities of modern science, there would be added to the expectation of life at least one and one-half years at age 45.

#### Need Inspection of All

The period between 45 and 55 is the crucial period in man's life, the time when degenerative processes begin to undermine the inherent vitality. And here the death rate is steadily increasing, especially among the most active in professional and business life, and because of their importance to the community their loss is a distinct one when they pass away before their work is complete. As insurance men we must ask ourselves the question, "Is there not a way, a means whereby we can, to at least a perceptible extent, stop this loss?" Many, through overwork or too strenuous a life, become exhausted in vitality and are wrecked on the rocks of middle life. There are chemical and nervous causes for this physical deterioration. Paton holds that perfect metabolism of advanced life is governed largely by the internal secretions of the ductless glands. Emotions such as care and grief very powerfully influence ductless glands with the secondary effect of slow degeneration.

Life insurance companies must point out these facts and medical men must make the application of either cure or prevention. This must cost money, but the result attained will prove a great gain in the end. The

highest function of our government is not to make millionaires out of a few or to become wholly absorbed in governmental finances and affairs, but to advance to the highest degree the health, intelligence and morality of its citizens. The greatest asset of any nation or any life insurance company is the health of its citizens or members. Thousands are going on year after year without the slightest knowledge of the condition of their kidneys, heart, liver, digestive organs or blood pressure, paying no attention to these tired, overworked and long-suffering organs. This is persisted in by thousands who have no knowledge of the consequence. Regular examination will discover the tendency to trouble before it runs into disease. It is beyond doubt that this increase can be traced to our mode of living, with its nervous strain, our dissipation and our disregard of the need for daily rest and exercise, together with excesses and indiscretions in eating and drinking. If the urine could be examined at intervals of six months to one year, nephritis would be detected in its incipiency, and steps could be taken to bring about a cure before it become chronic and incurable.

In these strenuous times, if a man past 40 wishes to prolong his life, he should undergo a thorough physical examination every six months. Disease may be insidious and progressive for months or years before the sufferer is aware of the fact. Hence, at least a blood pressure and urine examination are necessary, because the individual imagines himself in perfect health. This will prolong life and decrease mortality after middle age, and at the same time it will be advancing the cause of humanity.

#### Negro Health Week Observed

The eighth annual observation of Negro "Health Week" was duly observed April 2 to 9. Lectures, moving pictures, child hygiene, the sanitation of public places, and community responsibility for health conditions marked the health demonstration. The Negro shared the general improvement in death rate, as shown by the census returns.

Girls who have been brought up in the Hospice of Mexico City which cares for 1,500 destitute boys and girls will be provided early this year with a home in which they may live after they have become self-supporting through trade or occupation learned at the Hospice.

# Milk as a Factor in the Nation's Health

## A Full Time Health Department is as Necessary as a Full Time Fire and Police Department

By J. G. TOWNSEND, SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

*Good health demands plenty of milk. It supplies the body with necessary materials in exceptionally healthful and economical forms. An abundant supply of good milk is of national importance.—C. F. Langworthy.*

IN A previous article,\* the factors necessary in safe milk production to prevent disease were briefly discussed, but this knowledge avails us nothing if, in knowing what to do and what not to do, measures are not taken to capitalize this knowledge, especially by the medical profession.

The education of our citizenry is the mightiest weapon at our command, not education in its narrow, restricted sense—for the average, thinking individual resents in a degree being advised he needs education—but an honest effort to bring the milk problem before him in such a way that he may properly visualize its true significance. This vision by all of what safe milk means and what disease producing milk means would be a foundation stone in the building of sanitary reforms. Conversely, as told in Holy Writ, "Where there is no vision, the people perish."

### We See What We Are Taught

There can be no better place to initiate this visualization in the human mind than in the schools as soon as the child is old enough to grasp and appreciate what is being taught. The teaching of hygiene and public health in our schools as a part of the curriculum is becoming more intensive and is encouraging, but it is doubtful whether enough stress is placed upon the "milk question." In the presentation of these vital facts to the children in the schools, some seed will fall on fruitful soil, and future dairymen, milk producers, and milk products manufacturers will have inculcated in their minds sanitary laws, which should be as inviolable as the laws of right and wrong.

How milk should be produced to save or prolong the life of the baby is what every mother has the inherent right to know, but how can she know unless the medical profession aids her

in realizing these things? Lectures, moving pictures, interesting pamphlets, and newspaper stories provide ways and means to tell the milk story to the public. The National Government is cognizant of this and has distributed literature on the subject. The Department of Agriculture has ten suggestions for milk consumers, outlined in a pamphlet, as shown below:

### Ten Suggestions for Milk Consumers

#### Keep Milk Clean, Covered, and Cold.

1. Buy only the best milk obtainable. It is cheapest in the long run.
2. Consult the health department before selecting your milk dealer.
3. Buy only bottled milk if possible. Dipped milk is often dirty and deficient in cream.
4. Take milk into the house as soon as it is delivered, and place it in the refrigerator immediately. Bacteria increase rapidly in milk which stands in the sun or warms up, and such milk will sour quickly.
5. Keep milk in the original bottle in the refrigerator until the moment of serving. Milk which has been poured from the bottle should not be returned to it.
6. Keep the bottle covered with a paper cap or an inverted tumbler, to prevent the entrance of flies and dust, which may carry dangerous bacteria into the milk.
7. Keep the refrigerator clean and sweet by means of proper drainage and frequent washing with scalding water and sal soda, since milk quickly absorbs unpleasant odors and becomes less palatable.
8. Wash milk bottles as soon as emptied, by rinsing first with lukewarm water and then with hot water. If there is an infectious disease in your house, do not return any bottles except with the knowledge of the health department and under conditions which it may prescribe.
9. Return empty bottles promptly, and do not use them for anything except milk. Remember that they are the property of the dealer and represent cash.
10. Remember that clean milk, properly cared for, is one of the best foods obtainable. It is nourishing, digestible, and usually economical.

UNITED STATES DEPARTMENT OF  
AGRICULTURE,  
Bureau of Animal Industry,  
Dairy Division.

#### Keep Milk Clean, Covered, and Cold.

The United States Public Health Service is constantly alert to the necessity of raising the milk standard, and much literature on the subject has been, and is now being, distributed to those who are interested. The following pamphlets are indicative of what the Public Health Service has to distribute on this health problem:

Safe Milk. An Important Food Problem. Supplement No. 31 to Public Health Reports.

Milk and Its Relation to the Public Health. Hygienic Laboratory Bulletin No. 56.

Report of the Commission on Milk Standards Appointed by the New York Milk Committee. Reprint from Public Health Reports, No. 78.

Methods and Standards for the Production and Distribution of "Certified Milk." Reprint from Public Health Reports, No. 85.

A Homemade Milk Refrigerator. Public Health Bulletin, No. 102.

Standards for Determining the Purity of Milk. Reprint from Public Health Reports, No. 295.

Standards for Milk. Their Necessity to the Welfare of the Dairy Industry. Reprint from Public Health Reports, No. 318.

Relationship of Milk Supplies to Typhoid Fever. Reprint from Public Health Reports, No. 380.

Diphtheria. An Epidemic, Probably of Milk Origin, at Newport, Rhode Island, and Vicinity. Reprint from Public Health Reports, No. 430.

Dried Milk Powder. A Review of British Experience. Reprint from Public Health Reports, No. 473.

Treatment and Disposal of Creamery Wastes. Reprint from Public Health Reports, No. 496.

Safe Milk for the Small Town. Reprint from Public Health Reports, No. 497.

Dried Milk Powder in Infant Feeding. Reprint from Public Health Reports, No. 588.

Studies of Reconstructed Milk. Reprint from Public Health Reports, No. 608.

Commission on Milk Standards. Reprint from Public Health Reports, No. 634.

Antineuritic Vitamine in Skim Milk Powder. Reprint from Public Health Reports, No. 689.

The Growth-Promoting Properties of Milk and Dried-Milk Preparations. Reprint from Public Health Reports, No. 690.

In the rural sanitation studies, as conducted by the United States Public Health Service, much attention is paid to the milk question by lectures, personal talks, and visits to dairies and creameries.

During the late war, when the Service had charge of extracantonment areas, or zones five miles around the camps in this country, much stress was laid upon the importance of pure milk delivery to the military forces and civil population. This work was actively carried on in fifty-one zones in all parts of the United States and much propaganda for better milk was inaugurated and many

\*The previous communication on this subject was presented in the February issue of THE NATION'S HEALTH. Approved for publication by the Surgeon General.

inspections accomplished toward this end. In many places, the work was continued by the local authorities after the Public Health Service officers completed their work at the close of the war.

The group picture in Figure 1, showing various phases of the milk

supplies in the various cantonment areas:

Special emphasis was laid upon the sanitary condition of the dairies. It was demanded that the barns and milk houses be remodeled or rebuilt to meet an approved standard. A sanitary method of excreta disposal was instituted and general sanitary condi-

establishment of many new pasteurizing plants and the remodeling and enlarging of previously existing ones. It was urged that all restaurants, soda fountains, cafes, hotels, etc., use pasteurized milk delivered in original containers.

The Government is interested, and, through its appropriate departments, is doing its best to practice preventive medicine along these lines, but, in the last analysis, the problem is one for the local communities to solve through the state and local departments of health.

Health Supervision Side-Tracked

Adequate full-time health officers, with dairy divisions in the county and city health departments, are by no means common. It is all too frequent to find in cities, with populations ranging from 25,000 to 150,000, a part-time health officer, and that is all, placed in office for political reasons, engaged in a busy private practice (which takes practically all of his time), and yet, as a side issue, responsible for the health of the community. It is all wrong but, no doubt, will continue until it is more thoroughly realized that a full time health department is as necessary as a full time fire and police department and that the prevention of death is of equal importance with the prevention of fire or theft of personal belongings.

Full Compliance Necessary

The full time health officer can do much in spreading the gospel of safe milk production by the means already indicated, by tactful, sympathetic inspection of dairy farms, and, of most importance, by untiring efforts in perfecting the passage and enforcement of a milk ordinance. The provisions of a milk ordinance, in detail, depend somewhat on local conditions, but fundamentally should prevent fraud in adulteration and insist on milk production according to measures outlined in the previous article. A milk ordinance should not be too "wordy" but clear, concise, and to the point, stringent enough to exact full compliance before milk or milk products can be brought into the community, but not to extremes, whereby unnecessary hardship will result in this vital industry to the producer, or which make it difficult in enforcement by the health officer.

Inspections of dairy farms are, of course, necessary, the number of inspectors depending upon the amount of appropriations to the health department. At these inspections, each

Fig. 1. This group picture was used by the Public Health Service during the war to illustrate an article in a camp magazine.

industry, was published, with an appropriate article, in the weekly magazine of one of the largest mobilization camps in the country during the war. The men in this camp were from the West and a number of them were, in their way, very familiar with dairy farms, but this article published in their own military magazine put the matter before them in a new light, so that many of them in the dairy business could put into effect, as a peace measure, what they had learned as a war measure.

To quote from the Secretary's Annual Report to Congress (fiscal year, 1919), relative to the assistance given the local authorities by the Public Health Service in the control of milk

conditions bettered. A physical examination of all employees and milkers, together with vaccination against smallpox and typhoid fever, was also required. In many cases where tuberculin testing of cattle was not already required this was instituted.

Many improvements in the methods of producing milk were inaugurated, special emphasis being placed upon —1, all udders being thoroughly cleaned before milking; 2, all milking done with dry hands or modern mechanical milking apparatus; 3, the use of the small top milk pail; 4, properly straining the milk; 5, proper cooling; 6, proper sterilization of utensils; 7, prompt delivery.

The importance of properly supervised pasteurization was made plain to the producers and handlers of milk, and in all instances possible this was insisted upon, which resulted in the

Fig. 2. Filter pads, showing residue from various grades of milk; 10 to 9 represent milk from ideal farms. It is left to the imagination to picture farms producing milk of Grade 0.

dairy should be scored on an approved form as to cleanliness, methods of operation, etc., and the dairyman advised when he is not complying with the terms of the local ordinance in force relative to milk production. These inspectors must be high type men, men who know the business and its practical working, who can tell the dairyman how to correct unnecessary practices by constructive criticism, who, knowing the psychology of the dairyman, can deal with him in a kindly, helpful way, but firmly, so that the milk producer will do the right thing because it is right and not merely because the law provides he must do it in order to stay in business.

Milk should be inspected upon its entrance into the community governed by the milk ordinance, and samples taken for bacterial count and temperature. Milk registering higher temperature than that allowed by law should not be allowed to be sold.

The inspection reports and the record of successive samples give the health officer an index on all dairies supplying his territory and after a while he knows in a general way what to expect from each one.

One of the best methods to exact compliance with the milk ordinance is the arrest and punishment by fine of those who regard the law lightly and who willfully violate it. In this regard, the importance of the "question" must be appreciated by the judiciary, who, in sustaining the conscientious health officer in his efforts by imposing sentence on the guilty dairyman, play a signal part in this public health drama. (The drama is often a tragedy when the parts are not properly played.)

It has been my experience in health work that a few good fines in court, as reminders that a milk ordinance is not to be regarded lightly, go a long way in insuring sanitary milk production on the farm. Aside from the financial loss which occurs to the dairyman, there is a certain amount of business embarrassment due to unfavorable publicity, which naturally follows, and, as such sentences are rare, it is safe to assume that much publicity does follow.

A rather spectacular and very forceful method for the local health officer to utilize in obtaining public support for better milk is by the use of the "sediment test." This test consists in pouring the contents of a milk bottle through a cotton filter pad, which fits over the mouth like a cap, and all foreign substances such as manure, hair, organic dust, etc., are held in the meshes of the filter and show up plainly on the white background.

Figure 2 represents filters containing sediment in various degrees, graded accordingly. It is not hard to imagine how milk is produced which filters through the pad marked zero, and, conversely, dairymen should be credited with the type of their product, as indicated by filters marked 10 to 8.5.

It is easy to arouse public interest by placing on public display in prominent show windows a number of these filter pads containing residues of various descriptions. The pads should all be numbered and the respective dairies known by number to the health officer. Appropriate legends over these pads are useful, such as: "Are you interested in knowing how the milk you feed your baby is

produced?" or, "Pads showing dirt filtered from milk taken in this community, which pad represents the milk from your dairyman?"

In this way public interest is aroused by visible observations of uncleanliness, which it is impossible to demonstrate in speaking of bacterial uncleanliness.

The periodical publication of bacterial counts in the local newspapers has been resorted to and stimulates the dairyman to a keener competition in keeping his count down. This was most effective means during my service as health officer of a western city.

The "milk question" is ever with us and ever will be as long as milk occupies a place of dietetic prominence, as long as milk can carry in its wake disease and death, and as long as modern civilization brings local communities into closer contact and decreases distances between places more remote.

It is important that the measures taken to safeguard the supply should be common sense; adequate to obtain desired results, but not crippling to this vital industry. Indeed, those engaged in the production of milk and its products should be encouraged in keeping alive a clean, pure business.

The dairyman's life is hard. His overhead expenses are great and capital and equipment are necessary if he would put his product on the market according to modern health standards. The public, therefore, should be willing to pay a fair price for milk known to be safe, as it would for any other commodity of high grade and known value. A few cents more per quart for certified or inspected milk, as health insurance, may increase the span of life beyond the allotted four score years and ten or, at least, to that accepted goal.

### Hygienic Instruction in Public Schools

Recent announcements from Mr. D. J. Norton, director of health education in the Rochester, N. Y., public schools, indicate that self-governing and self-instructive methods of teaching hygiene to children in the public schools will soon be organized in every school in Rochester. Each grade will be organized into a club and each row of pupils in a room into a health team. A system of checking on health duties and of rewards for their performance is devised to stimulate the interest, and practical training in sanitary supervision will be included in the duties prescribed.

## Food Knowledge and Food Prejudice

LEGISLATION against the handling of filled milk through interstate commerce has recently passed the senate. Inasmuch as this law makes mandatory the distribution of the product within circumscribed fields and under fixed conditions, it definitely limits the use of an unquestionably useful and val-

upon legislative support, but that if the collective action is to be intelligent, or directed toward general improvement in such matters, public opinion must fortify itself at least with the fundamental facts, so that knowledge and not mere prejudice shall become effectual.

The incident recalls what happened

taches to the word substitute as well as the handicap of a discriminating tax of one-fourth cent per pound on the uncolored and ten cents per pound on the colored product. Nowhere else in the world is such a food tax imposed. The people are right to demand proper labels, adequate food values, and purity of product; but if the whole people are to have adequate rations, no source of the economical production of satisfactory foods should be cut off.

The opposition to margarin is waged on the basis of the vitamin content, no mention being made, of course, that the deficiency of certain fats is rated on the basis of animal experimentation on rigidly exclusive diets nor that any such deficiency, real or fancied, is readily supplied in a varied dietary. It is not brought out that the vitamin quotient is by no means constant in dairy products nor are they so uniform in standard as some of the manufactured products. Carter, Howe, and Mason<sup>1</sup> have expressed themselves on this point as follows: "Oleomargarin is a satisfactory substitute for butter; it is often more desirable than some good grades of butter. . . . Containing, as it does, a higher percentage of stearin, we might expect to find oleomargarin less readily absorbed than butter; experience has shown, however, that the losses in digestion are the same for the two products."

Oleomargarin is a youngster among

1. Carter, Howe and Mason: Nutrition and Clinical Dietetics, Lea & Febiger, New York, 1921.

The solid ingredients of oleomargarin are melted, mixed with the liquid oils, and churned together with milk. Later the surplus moisture is removed, and the small granules of the product are worked into a complete and plastic mass.

uable food material at a time when the nutritional needs of the country are such that the Nutritional Committee of the National Research Council has found it necessary to develop a cooperative plan for nutritional research in order to work out economic data on the whole subject of nutrition. The spirited debate that preceded the passage of the filled milk bill is highly interesting reading and reveals another cogent reason why the public, through food knowledge, needs to overcome certain definite food prejudices. The fight against filled milk was not waged against dried milk as such. It was not claimed that the product is improperly labeled, nor that it is impure, or that it is lacking in definite food values. The fight was based on the fact that certain fats other than dairy products are added to the manufactured product. It was held that improper use of the commodity might bring about untoward results, and, what was essentially a trade war, was waged,—and won—on a public health basis. All of which shows that wars waged on a public health basis may in this age of enlightenment count

some years ago when margarin, a wholesome and economical food, and one which enables the conservation of materials which would otherwise constitute waste, was legally saddled with the opprobrious term "substitute" and has ever since had to cope with the popular prejudice that at-

The milk is carefully tested by expert chemists and, if of satisfactory standard, it is cleaned and re-pasteurized. After cooling it is conducted through pipes to glass-lined tanks where other ingredients are added in measured amounts.

foods. It came into being the latter part of the last century. Considering how far back some of the essentials of our diet go, oleomargarin may well be classed with the younger generation of products. Most of the everyday staples of the dietary have come to us quite casually and without preliminary research. Oleomargarin, however, was first conceived as a scientific idea, then it became a subject of experiment, and finally evolved as a food. It was a scientific discovery to fill a definite need. It was achieved in France under the auspices of Napoleon, at the time of the Franco-Prussian war, by Mege Mouriés, a French scientist, who won a substantial reward for his efforts in this direction. Years of development have intervened between those days and now, despite trade opposition, the increasing public approval of the highly developed product springs not only from its fine flavor and good quality, but from a growing appreciation of the absolute sanitary control of the entire process by which it is made. Modern manufacturing methods, fundamental purity in every component part, government inspection throughout,—all these have made oleomargarin a food for connoisseurs. Every part of the process of manufacture is marked with infinite care and natural wholesomeness is characteristic of every ingredient.

Oleomargarin is made from oleo oil, neutral, and vegetable oils, salt, milk, and sometimes a certain percentage of the best creamery butter. The solid oils are melted, mixed with the liquid oils, and churned together with milk. After the mixture is chilled by contact with an ice water spray it is

allowed to ripen until the whole mass becomes permeated with the milk flavor, when it goes to the worker, where salt is added. In this process the surplus moisture is removed, and the small granules of the product worked into a complete and plastic mass. It is then ready to be packed into cartons or tubs. From the time the raw materials enter the plant until the freshly boxed cartons are packed into cases, no hand is allowed to touch the product.

ing the recent years its production has reached a point where it is about 40 per cent of the total product. The materials and the manufacturing costs are less and it is sold at a price lower than the standard price for oleomargarin made from animal oils.

There is no reason for current argument against supplementing the dietary with these manufactured products, nor for any remnants of prejudice against their use. All of the component materials,—salt ex-

The mixture is chilled by contact with an ice water spray. After the whole mass has been permeated with the milk flavor it goes to the worker, where salt is added. When completely processed, it is packed in cartons or tubs. No hand touches the materials from start to finish.

The process described involves the use of animal and vegetable oils, but a similar product is made from material entirely vegetable in character, principally the oil from peanuts and ripe cocoanuts. Seven or eight years ago nut margarin was an unknown article in the United States, but dur-

cepted, are found in practically every kitchen every day in one form or another and, separately, no question ever arises as to their wholesomeness or food value. Fat is essential in the dietary. Prepared fats are similar to the unextracted fats, for the processes of manufacture are essentially physical ones. The necessary amount of fat required per day is not exactly known, but the minimum has been estimated at from twenty-five to fifty grams per day. Fat is a much more concentrated food than carbohydrate or protein in the sense that it yields, because of its lower state of oxidation, a greater amount of energy for a given weight, fat yielding 9.0 calories per gram, or 4,082 calories per pound; and carbohydrates 4.0 calories per gram, protein 1,814 per pound. It is therefore the most economical means for storing energy against future need. Prepared fats are similar to the unextracted fats, for the processes of manufacture are essentially physical ones. Langworthy and Holmes in Bulletin No. 310 of the United States Department of Agriculture reported on the principal fats as follows:

Color, appearance, texture are factors of food values amply provided for in manufacturing processes. Pure milk, perfectly pasturized, scientifically ripened in rooms of white tile flooded with daylight, takes care of the natural flavor of the finished product.

Fats Studied—	Coefficient of Digestibility Per cent
Butter fat .....	97
Lard .....	97
Beef fat .....	93
Mutton fat .....	88

Both fats and carbohydrates are used chiefly in the production of energy. Their rôle in the structure of the body, while little understood, is highly important. A higher fat content is called for in the diet of those whose work is arduous. The fat content of the blood increases

during feeding for the absorbed fat is poured into the blood stream above the liver. The fat begins to be absorbed about two hours after ingestion and reaches a maximum in about six hours. The fat content of the blood is fairly constant except at times of active absorption from the blood. When large quantities of fat are being utilized, as in fasting or diabetes, there is often an increase in the blood fat. Because of their

relatively low vitamin content certain fats have been erroneously considered as thereby discredited for food, but in this connection it is to be remembered that these statements relate to the controlled and minimum maintenance rations of the experimental laboratory. Fats and carbohydrates are chosen for the energy values, and the vitamin necessities are easily taken care of in the ordinary American diet by the use of other foods.

## Digest of Sanitary and Hygienic Advance

THE comprehensive nature of sanitary science demands on the part of the health worker omnivorous reading and a selective talent for which the average health officer's busy life leaves little time to exert. Medical journals, civic publications, legislative reviews, laboratory abstracts, and of late even the popular magazines are featuring health projects as news. We present herewith a digest of several outstanding contemporary articles and some pertinent suggestions which should be of general interest:

**Seawater for Mixing Antiseptic Solutions.**—It sometimes happens that fresh water is not available for mixing solutions of antiseptics in quantity. In such situations seawater may be used with carbolic acid, formaldehyd, bi-sulphite of soda, thymo-formol, sulphate of copper, cyanid of mercury and oxy-cyanid of mercury, since these chemicals are unaltered by the action of salt water. Chlorid of zinc, bi-chlorid of mercury and the alkaline hypochlorites are actually improved by the action of sea water.

**"Millions" in the Control of Malaria.**—The use of *Gambusia affinis* or other carnivorous, viviparous fishes for the destruction of mosquito larvae is a measure of proved efficiency. Failures may be attributed to the escape of the "millions," their destruction by enemies or their hindrance by water-weeds or grasses. If the edges of ponds are cleared and if the surface-feeding fish are not disturbed by natural enemies, they will promptly destroy mosquito larvae. There are at least twenty-six species of fish in the United States considered suitable for use against the eggs and larvae of mosquitoes.

**Trees as Mosquito Breeders.**—In conducting anti-mosquito campaigns, it should be borne in mind that tree-holes such as occur in forks and clefts

are sometimes prolific breeding places and are frequently overlooked. A simple method of drainage is by siphons made of cotton waste and tacked in place.

**Formaldehyd as a Fly Poison.**—The efficiency of formaldehyd as a fly poison depends upon its freedom, when exposed to the air, of formic acid and methylamine. It should be colorless, free from fishy odor and neutral in reaction. The following formula

An arrangement which provides an acceptable manner in which to use fly poison. Flies cannot fall into the receptacle and the blotting paper permits constant access to the poison.

(*Bul. Entomolog. Research. Vol. XI, pt. 1*) is recommended:

40% Formaldehyd .....	5 parts
Clear Lime Water.....	50 parts
Sugar .....	2.5 parts
Water .....	42.5 parts

This is best used in a bottle shown above so arranged that flies cannot fall into it. This is necessary since their cadavers will render the solution acid in reaction. In the mouth of the bottle there should be placed a piece of blotting paper as shown in the accompanying drawings (Fig. 1). When formaldehyd solution is used as a fly poison it is quite necessary that no water be available in the room for, if so, the poison will go untouched.

This is important and has been experimentally demonstrated.

**Culture Medium for B. Diphtheria.**—Loeffler's medium has the disadvantages of opacity the requirement of large amounts of serum. Captain S. R. Douglas recently reported to the Royal Society of Medicine that he had secured the best results by the use of a 1 percent solution of potassium tellurite added to melted agar and used with trypsinized serum. The diphtheria bacillus colonies have black centres, contaminating organisms being practically colorless.

**A New Pediculicide.**—A non-toxic, non-irritating, inexpensive and efficient pediculicide with bile-salt as the vehicle is described by Peters in the *British Medical Journal* of February 18, 1920.

The compound consists of:

Sodium taurocholate.....	10 grams
Ol. eucalyptol.....	50 grams
Water to.....	1,000 c.c.

Dissolve the bile salt completely in water, add the eucalyptus oil, and shake well.

To use, rub in thoroughly until the hair is completely wet. Put on a rubber bathing cap or wrap the head in a towel. Leave on over night and in the morning wash well with soap and water. A fine tooth comb is used daily for two weeks.

In a series of more than five hundred cases, Peters noted in 23 per cent, a second application was unnecessary; two treatments were required in 63 per cent and a third application was necessary in the remaining 14 per cent. The formula has as its underlying theory the fact that bile salts assist the passage of emulsions of fats through membranes by lowering surface tension and hence assist the penetration of the louses eggs by oily emulsions. The non-inflammability of the mixture and the fact that it destroys all forms except the most re-

cently deposited eggs, add greatly to its value.

**The Closure of Schools on Account of Infectious Disease.**—Despite the fact that the strategic advantages of the school in the control of communicable disease has been recognized for a number of years, whenever there is an outbreak of epidemic disease, almost the first control method urged by the general public is the closure of the schools. In remote rural situations where the school constitutes the main contact point for the area or when the bulk of the teachers are afflicted with the prevailing infection, it is a measure worthy of consideration. As a rule, and particularly in urban centres, the idea will be quickly dismissed by the thinking health officer who realizes that by such an act he deprives himself to a large extent of an accurate knowledge of what is going on in a large and important block of the population, thus hindering very considerably follow-up work and other control operations. Furthermore, the idle children roam the streets at such times thus estab-

lishing a multitude of fresh contacts for the reception or distribution of the prevailing disease. Sometimes the health officer will be overridden by the popular clamor but he should steadfastly resist attempts at school closure on account of an epidemic.

**How Long Is Measles Contagious?**—M. Baur (*Münch. Med. Woch.*) states that while the incubation period of measles, 13 to 14 days, is well recognized, the contagious period is less well defined. He had the opportunity of studying carefully the question at the clinic of the University of Cologne and concludes as the result of this epidemiological investigation that the contagious period is limited to the catarrhal stage and the first day or two of the eruption. He places the period of maximum infectiousness at the time when the prodromal stage is just ending and the exanthematous stage is just beginning. He believes that the disease ceases to be contagious twenty-four hours after the appearance of the eruption. In this connection the studies on experimental measles reported by Duval and D'Au-

noy in the *Journal of Experimental Medicine* (1922, XXXV, 2, p. 257), are interesting. These research workers found that thirty-six hours prior to the eruption and twenty-four hours after the temperature became normal, guinea pigs did not react to the blood of human measles cases, and that the guinea pig reaction is produced with human blood during the stage of eruption. This would seem to indicate that prolonged isolation is not required in the prevention of the spread of measles.

**Herpes Zoster and Varicella.**—While a Scotch verdict must still be rendered on the question of the identity of or connection between varicella and herpes zoster, a considerable amount of data indicating that the relationship is much more than accidental is accumulating. The occurrence of the disease in persons who have been in close contact with herpes zoster cases and the apparent immunity of persons who have had herpes zoster to varicella infection has raised the question if at least some cases of shingles are not aberrant forms of varicella.

## The Whys and Wherefores of Sleep

**W**HY an individual must sleep away one-third of his existence no one has yet satisfactorily explained. What is sleep, anyway? Is it, as Marie de Manacéine puts it, merely "the resting time of consciousness" and the lowering of physiological processes becomes possible only when the dominating desires of the waking hours are held in abeyance? Mosso states that the amount of air inspired is one-seventh of that used during a period of quiet wakefulness. Amar says that the static expenditure of energy is in sleep about fourteen-hundredths of that in waking hours. Carbonic acid elimination is decreased, while the absorption of oxygen is increased. The heart beats more slowly; the pulse is less rapid, and the general arterial pressure is lowered. The brain is anemic, while the blood supply to the skin is greatly increased, which accounts for the increased production of sweat. The internal temperature of the body is lessened. The movements of the stomach and intestines are enfeebled. All the secretions of the body are diminished, save those of the skin.\*

It is significant that, while the purposive activities of mankind are fatiguing, his physical automatizations pursue their ordered rhythms without pause and without fatigue. What part of the body rests during sleep? Is it not true that, asleep or awake, the heart pumps its stream, the lungs expire and inspire, and the stomach, liver and other organs perform their functions? The skin is practically twice as active during sleep as during the waking state, and even the hair and nails continue to grow. Is not hearing still acute, as proved that any sound capable of attracting the attention during the waking period will disturb the sleeper? Will not unsavory odors, or badly tasting material placed in the mouth, awaken the slumberer? Do not dreams show the mind to be active? Do we not change position, are we not conscious of pain, do not persons sleep on horseback, etc.?

### Physiology of Sleep

Sleep is rhythmically recurrent and a necessary function. Loss of sleep is worse than starvation. Animals deprived of food for twenty days and which have then lost more than half their weight, may still be saved by

judicious feeding; but, completely deprived of sleep, they die in from four to five days, and this in spite of the most careful feeding and other care. The biologic theory of sleep, formulated by Clapardé, supposes that sleep is a defensive factor of the body and that its purpose is to ward off fatigue. Repose and sleep are considered to be the inevitable consequence of the law of rhythm which appears to govern life and which constitutes its means of defense. Many observations of the phenomena of sleep have been made incidental to studies on fatigue. Massage and sleep are among the influences which Amar states as favoring muscular power. Massage or kneading of the muscles repairs them. Sleep also is restorative. Theoretically, the energy expended by the muscles in work should be capable of restoration by increasing the amount of ailment, but this cannot replace sleep. Amar's experiments indicate that at least seven hours of sleep are necessary to re-establish the forces which have been upset by a day's work. It should be at night and free from disturbances, he says.

From the standpoint of fatigue there is a considerable body of ex-

\*The facts on the physiology of sleep in this article are drawn from "Yours for Sleep," by William S. Walsh, M.D., E. P. Dutton & Co., New York, 1920.

periment in regard to the profitable length of a school day, and of a work day, but very little expert advice as to the amount of sleep required as a restorative. Walsh is inclined to consider twelve hours as necessary at the age of four years, ten hours between the ages of six and ten. From the ages of ten to sixteen years at least nine hours are required and adults as a rule must sleep at least seven or eight hours out of twenty-four in order to retain their equilibrium. In old age the requirements are less. In cold climates more sleep is required than in warm or temperate climates. The first few hours of sleep are the deepest, and the amount of sleep indulged in should be gauged to suit the individual rhythm.

### Psychology of Sleep

Psychologists have long been inclined to regard sleep as an affair of the mind, to consider disturbances of sleep as varying degrees of consciousness, and to interpret the uncensored dream thoughts in terms of the real, though perhaps unconsciously hidden, wishes of the subject. Dreams not pleasurable and which are remembered are detrimental in many ways. They interfere with sleep, or, if the sleep remains unbroken, the nutrition and repair going on at the time deviate from the normal. Again, harassing dreams may be equivalent to a shock during the waking state. Certain types of dreams may indicate an unstable nervous system, or may be the forerunners of disease. They are matters for the consideration of the physician rather than the psychologist. Since wishes have themselves been reduced to the physiological basis of segmental tensions, barring physiological disorders, it is safe to ignore the vagaries of the dream interpreter and address ourselves to the conditions of sleep and the factors which favor restorative slumber.

The mind, however, must be considered in sleep processes. The farther away from the brain a member is, the more lightly it sleeps. A sleeper can be awakened more easily by tweaking his toe than by touching his face or head. Fifty-nine per cent of persons can awaken any time they decide upon before going to sleep. To prove mental control even during the sleeping condition Rivers, apropos of the selective action of certain conditions of awakening, cites the doctor who is awakened even by the movement of wires which precede the ringing of his night bell, while he is undisturbed by the crying of his child

to whose slightest sound the mother immediately responds. Awakening is determined, not by physiological demands, but by predispositions of a psychological kind.

### The Hygiene of Sleep

This perhaps accounts for the fact that suggestion forms an important part of almost any treatment for insomnia. Belief in their ability to sleep is absolutely essential for those whose insomnia is the result of mental causes. Normal sleep, according to Walsh, is a gift we all have had at one time, and may still have. Since normal sleep is gauged appropriately to the internal bodily rhythms, it is necessary to retire at a regular hour. Mental habit has much to do with it. Effects of light and sound which disturb cerebral quiet are to be eliminated. Rattling window blinds or other defects should be remedied. The walls of the bedroom should be restful and neutral in color. The bedding should be as simple as possible, not too absorbent, but of a nature easily kept in a sanitary condition. The coverings should not be heavy. Several thin coverings are better than a single one of equal weight, since the air that readily finds access between them is not conducted. The sleeping room should be airy. "Nail windows open," says Walsh. The temperature of the bedroom should preferably not exceed 60 degrees.

### Posture and Sleep

Psychologists say that dreamless sleep does not occur, a statement they would find hard to prove. But if dreams are the expression of wishes, and wishes are segmental tensions, then the question of posture during sleep, and the choice of a bed that both supports and yields according to the requirements of the situation, become of primary importance. On what side of the body should we sleep? Most people prefer the right side, but this is largely a matter of habit. Popular opinion holds that by this cardiac action is not embarrassed and the emptying of the stomach is facilitated. Some observers think that the reason inflammation of the right lung is more frequent than that of the left is due to the fact that lying on the right side favors stasis of the blood on that side. Inflammation of the bases of the lungs occurs more often than of the apices, again referable in some cases to posture in sleep. Sleeping on the back is a fruitful source of dreams, probably due to interference with the cerebral circulation, secondary to a compression of

the abdominal aorta. Which side to sleep on is, after all, but a minor point. We must choose one side, and there is no weighty reason why one side is not as good as another. On the subject of posture in sleep Walsh says:

Individuals in good health may be able to sleep comfortably without pillows. This practice, which is to be encouraged, tends to prevent round shoulders and contributes to a cure when such a condition arises. Lying prone with one arm extended above the head and the leg opposite drawn up, which attitude may be repeated on the opposite side, can take the place of pillows. Posture during sleep is a matter of no great importance. One pillow, small, flat, and moderately hard, should be enough for most individuals. In cases of sleeplessness due to arteriosclerosis even three may be necessary. In arteriosclerosis it is common to be sleepy in the daytime and wakeful at night, because the recumbent position sends more blood to the brain. A semi-erect posture, therefore, favors sleep in such cases.

With regard to waking, Walsh says: "Remembering that sleep tends toward a stasis of blood in the various larger organs and in the extremities, we should, before arising, lie on the right side a few minutes, then on the left, then on the stomach, and finally on the back. This simple practice is often very efficacious in removing the angina pains, asthmas, lumbagoes, so often found in anemic individuals and which are often due to improper positions during sleep. The muscles can then be gently exercised by stretching, after the manner of a yawn, so as to remove the stiffness then existing in them occasioned by repose. It also serves to minimize the slight shock accompanying a sudden change to the upright position. A few minutes exercise on getting up, taken preferably in the open air, starts the day right.

There is no specific for insomnia. The underlying cause must be ascertained and removed before a cure can be expected. Even then the ability to sleep often needs to be wooed back. There is an art in making yourself comfortable and also an art in procuring pleasant dreams.

### Cancer American Plague

Cancer, which kills 80,000 persons in the United States each year and has a 90 per cent mortality of all those afflicted, has become the great American plague, states L. Duncan Bulkley, M.D., in *The Medical Record*. Against the 5,656 deaths from cancer in New York City, there were only 5,225 deaths from tuberculosis, an excess of 431 for cancer.

## Can White Men Live in the Sun?

THE baneful effects of too much sunlight on the white man is discussed by Chas. H. Huestis, M.A., D.D., of Red Deer, Alberta, in the *Canadian Journal of Medicine and Surgery*.

The belief in the benefits derived from the sun's rays is of recent origin and not derived from the history of the race which points out the reverse. Animal life was of aquatic origin. The water, absorbing the ultra-violet rays of sunlight, protected the cells which could not otherwise have existed. Most animals are nocturnal in habit, passing the day in sleep and the night in prowling. The negro prefers to sleep in the daytime, coming out at night to dance and sing under the moon. Animals that live in the daylight are protected from sunlight by fur and feathers and by pigmentation of skin.

Such instances tend to prove that nature and instinct protect animal life from too great stimulation by sunlight, indicating that while small quantities of sunlight are doubtless beneficial, in large measure they are harmful and even fatal.

In the case of man, reason enters in to contradict instinct. Even then the distribution of the races upon the earth bears out the fact that the skin of man is dark or light in proportion to the sunniness or cloudiness of the land which is his true habitat. Cloudy, foggy lands are inhabited by big blonds; sunny lands by little dark men.

The modern craze for sunlight is extremely harmful, Mr. Huestis believes. A baby exposed to the sunlight on doctor's orders is apt to be over stimulated which results later in anemia and arrested development. Likewise much eye trouble in children is due to this undue exposure to the sun.

The custom, too, of placing hospitals so that every room is flooded with light for as much of the day as possible is not good therapeutics in the opinion of Mr. Huestis. Better the protection of the patient from the too stimulating rays of the sun.

White men have never been able to live permanently in sunny countries, the writer points out. India, which has been ruled by white men for generations, has no third generation of whites. White men conquered the Indians in North America. Under its sunny skies there has developed an aggressive force unparalleled in the history of the world,

but this over stimulation has produced nerve exhaustion. In Alberta, Canada, effects of long continued sunshine are apparent. Newcomers at first feel a great urge to activity but after a few years the disintegrating result of the actinic rays of the sun is felt.

The writer believes that white men will not be able permanently to colonize west Canada outside of British Columbia west of the mountains. But the evil effects of sunlight may be mitigated so as to make life there more endurable. The typical house of the west, the bungalow built on the ground with wide shaded verandas, is the right sort of house. Windows should be protected by green blinds or shutters which can be closed during the sunniest parts of the day

but will admit ventilation. Tree planting would be of great aid for trees absorb much sunlight as well as afford shade.

The school day should be shortened and the school year rearranged so that examinations would come in April. Habits should be changed with more emphasis on rest and relaxation. In the matter of dress it would be wise to imitate inhabitants of the South. If white is worn as an outer garment, the under garments should be black or yellow to intercept the sun's rays. The warm bath should be substituted for the cold plunge so popular with Britishers as the latter is too stimulating.

In conclusion, the author states it as his opinion based on history and observation that it is doubtful if white men, especially those of light complexion, can long survive in a sunny country.

## London Graduate Medical Work

MENTION has been made previously to the somewhat belated efforts on the part of some of the members of the medical profession to make London a center for medical postgraduate training in Europe. Before the war there was practically no postgraduate instruction of an organized nature in London. Berlin, Vienna, and Paris, to a lesser extent, held sway in this field, Berlin and Vienna catering especially to American medical men who were desirous of learning European methods of medicine and surgery.

At that time the British medical profession seemed not only indifferent to attracting foreign and American postgraduate students to their schools of medicine and hospitals but paid only slight attention to postgraduate training. That wonderful original thinker and skillful surgeon, the late Jonathon Hutchinson, with the foresight which was one of his most distinctive characteristics, was impressed with the need for maintaining medical and surgical knowledge up to date and was instrumental in founding the London Polyclinic. But the profession was generally lethargic and the scheme languished, in fact, was almost stillborn. However, after the war some earnest and energetic medical men and surgeons, prominent among whom were Sir Arbuthnot Lane and Mr. Philip Franklin, an American-born nose and throat specialist practising in London, saw the possibilities, when Berlin and Vienna

were *hors de combat* at least temporarily, of London taking their place. The Fellowship of Medicine and Post Graduate Medical Association were established with headquarters at the house of the Royal Society of Medicine, the secretary of which Sir John Macalister was enthusiastic for the carrying out of the project.

At last a definite move has been made in London and courses have been drawn up. Hospitals cooperating in the plan are: Bethlehem Royal Hospital, S.E.; Cancer Hospital, Fulham Road, S.W.; Chelsea Hospital for Women, Arthur Street, Chelsea, S.W.; Hospital for Consumption and Diseases of the Chest, Brompton, S.W.; Hospital for Epilepsy and Paralysis, Maida Vale, W.; Middlesex Hospital, Berners Street, W.; National Hospital for Diseases of the Heart, Westmoreland Street, W.; Paddington; Green Children's Hospital, W. Royal Westminster; Ophthalmic Hospital, King William Street, Charing Cross, W.C.; St. George's Hospital, Hyde Park Corner, S.W.; St. Mark's Hospital for Diseases of the Rectum, City Road, E. C.; St. Mary Ebene General Dispensary, 77 Welbeck Street, W.; St. Peter's Hospital, Henrietta Street, Covent Garden, W. C.; Western Hospital, Seagrave Road, Fulham, S.W.

The foregoing hospitals gave a six weeks' course in general medicine held from January 9 to February 18, 1922. A syllabus of a surgical course will be issued soon.

## Jules Schevitz, 1898-1922

We have to announce the death in Oklahoma City on March 22 of Jules Schevitz, a member of the Board of Editors of *THE NATION'S HEALTH*. The death of Mr. Schevitz cuts off a promising career in public health. He was only twenty-four years of age, yet he had impressed his work upon the country and was known in all health organization circles. He studied health work under Dr. T. W. Sedgwick at the Massachusetts Institute of Technology; went to Oklahoma in 1918 where he built up the splendid Public Health Association of that state, meanwhile serving as a member of important national health committees. Mr. Schevitz had been for some time a frequent contributor to *THE NATION'S HEALTH* and for some months had been identified as a member of the Board of Editors.

## The Rising Tide of Heart Disease. Remote Conditions Involved.

ALMOST 11 per cent of the total number of deaths in the Registration Area of the continental United States in 1920 were, according to the Bureau of the Census, the result of organic diseases of the heart. This is an increase of 1.5 per cent since 1910. In that year the death rate from heart disease per 100,000 of population was 141.5; in 1920 it was 141.9; it is in the proportion of heart disease deaths to

deaths from other causes that the real increase has occurred.

Any disease-group causing such a percentage of the total number of deaths is worthy of careful analysis and the application of definite measures looking toward reduction. Accurate analysis of these figures is not possible, nor is it absolutely necessary since, after all, vital statistics are not surveying transits but signposts indicating in a general way the direction toward which the body politic is tending. It may therefore be said that, while the rate is only slightly greater than it was a decade ago, a study of the percentage of the total deaths shows that pneumonia is the only single item which, as a Captain of the Men of Death, approximates that of organic disease of the heart.

From the epidemiological viewpoint this classification is of little informative value, since it is based upon a pathological and clinical condition rather than upon the cause itself and, before any well planned campaign for the control of organic heart disease can be launched, some knowledge must be had of the factors in its production.

There has been a tremendous advance in the clinical diagnosis of these conditions, the methods and instruments of physics having, so to speak, opened the pericardium for the internist to view exactly what is taking place in the living heart. This, with the increase in the number of necropsies, serves to emphasize the important place of heart disease in the production of mortality. The average practitioner makes far more careful reports of death than formerly and the registration area now embraces 82.2 per cent of the estimated population of the United States. This makes it possible to collect more accurate data regarding the prevalence of organic heart disease and this makes it appear as if there was a larger number of deaths from cardiac lesions every year. Whether or not this is true time and study alone can tell, but it would be remarkable in view of the way in which the infectious diseases are being controlled and eradicated, if there was not a coincident reduction in the death rate from heart disease, since this condition is in the vast majority of cases a secondary process supervening usually upon some remote infection.

This renders the mortality statistics for heart disease exceedingly misleading. It is as though death certificates reading "Primary cause: organic disease of the lungs. Secondary cause: tuberculosis" were accepted by registrars of vital statistics. If all deaths were listed according to the remote rather than the proximate cause, there would be a corresponding increase in the proportion of deaths from syphilis, gonorrhoea, scarlet fever, and the other infections, with a simultane-

ous fall in the percentage of deaths from heart disease.

The child hygiene movement and the anti-venereal campaign, no less than the other measures for the improvement of the public health, will undoubtedly reduce the amount of heart disease in the future. In fact, a comparison of the vital statistics of the past with those of recent years, indicates that there has been a reduction in the percentage of deaths from heart disease up to the fiftieth year of life, with a corresponding increase thereafter. This may mean an improvement in the methods of treatment or a better safeguarding of the damaged heart by the instrumentalities of public health. Whatever may be the cause, it is an index of the increasing security of human existence.

The practising physician may do much toward placing the statistics of heart disease on a more accurate basis, by reporting deaths under the original cause, whenever it is possible to determine it. He also should recognize the danger of a mild heart affection in childhood becoming an organic lesion in adult life if neglected in youth. A great many of these accidents of after years may be prevented by the careful regulation of life during the period of convalescence from the acute infections.

---

## The Training of Public Health Workers

THE conference on the future of public health and the education of sanitarians held under the auspices of the United States Public Health Service at the American Red Cross Building in Washington on March 14 and 15 promises to be an important landmark in the history of the public health movement. All the prominent public health educators of the country and many of the leading public health officials were represented in the discussion, the conference members including seven college presidents, twenty-six deans and directors of schools of hygiene, public health and medicine, thirty-three professors of public health and allied subjects, and such typical representatives of the practical public health movement as Doctors Armstrong, Biggs, Brown, Cumming, Frankel, Fronczak, Ireland, Kelley, Levy, Lumsden, McCormack, McLaughlin, Snow, Stitt, Vaughan, Vincent, White and Williams.

The first session was devoted to a review of past developments and present standards in the education of public health workers with special emphasis on some of the newer aspects of public health work such as mental hygiene, child hygiene, the economic aspects of public health, phy-

sical education, industrial hygiene and public health education. In the second session an attempt was made to outline the qualifications for the public health worker of the future in which it was made clear that the most vital problem is the production of what was called "the general practitioner of public health." Next followed a discussion of the reasons for the deficiency of trained sanitarians and of methods by which the public health career can be made more attractive. The Wednesday morning session was devoted to a discussion of the details of courses which should be included in the curriculum of the public health expert with special emphasis on the importance of directed field work under actual working conditions, which is the analogue of the clinical training received by the medical student in the hospital. After a series of concluding addresses, Dean Edsall of Harvard summed up some of the more important points at issue, and a permanent committee of nine members<sup>1</sup> was appointed, with power to enlarge its number to fifteen, to consider "whatever questions it sees fit and take whatever action for further conference may seem wise in order to continue the activities that this conference has started."

The conference did much to clarify the present situation and to inspire its members with a new realization of the importance of their task. It is quite clear that the principal obstacle in the path of the public health movement is the lack of sufficiently numerous well trained leaders. There are three factors in this problem: the man, the school, and the job, all of which are in need of improvement. Schools of public health have grown up in many universities during the past few years and are probably today able to train more and better men than are available and to fill more and better positions than are open to their graduates. Yet the education given by these schools is in great need of standardization and improvement particularly along the line of practical field experience. The public demand for trained health workers while behind the potential capacity of the schools of public health is probably ahead of the actual supply of good material. Here, too, however, the public must come to a realizing sense of the need for securing security of tenure and liberal compensation to a class of experts more practically important to the community than any others which it employs. The weakest link in the chain is, however, the supply of suitable candidates and in particular we need to recruit a much larger proportion of the ablest young men

1. Dr. C. C. Bass, New Orleans; Dr. D. L. Edsall, Boston; Dr. W. H. Howell, Baltimore; Dr. E. O. Jordan, Chicago; Dr. A. J. McLaughlin, U. S. Public Health Service; Dr. M. J. Rosenau, Boston; President R. L. Wilbur, Palo Alto; Dr. E. G. Williams, Richmond; Professor C.-E. A. Winslow, New Haven.

graduating from the medical schools of the country. Professor Jordan presented to the Washington conference a most disheartening series of replies to a questionnaire addressed to the students in four leading medical schools showing the lack of knowledge of the public health field and a failure to realize its potentialities of service. Perhaps more than anything else we need a campaign of education to enlighten medical students in regard to the field of public health and to interest those of them in whom the social viewpoint can be awakened, in the still largely untilled fields of public health.

---

### Investigating the Effect of Occupation on Health

GRATELY widened limits of inquiry into statistics and into the underlying causes of disease must be placed to the credit of industrial medicine. It is not too much to say that the necessities of industrial medicine may require the entire reorganization of our health statistics as without it no proper check may be had on the physiological effects of occupation and therefore no adequate estimate of the value of medical service. The need to base conclusions on morbidity investigations rather than on mortality rates as in the present system is brought out in the recent address of R. E. Risher<sup>1</sup> before the Royal Statistical Society in London. Mr. Risher reviewed the difficulties which countered the attempts of the Industrial Research Board to make an accurate study of industrial morbidity. Based upon statistics referring to the iron and steel trade, the boot and shoe industry, and the laundry trade, he concluded that (1) age has the greatest influence upon morbidity, and next to this, occupation; (2) occupation has more influence than has either locality or density of population, but the influence of the latter cannot generally be dissociated from that due to occupation; (3) there are no reliable statistics in this country (England) of morbidity among female lives; (4) no statistics exist of the sickness experienced by the community at large corresponding to those published concerning mortality.

The advantage of investigating the causes of morbidity in any particular occupation is that, were any given industry shown to have an excess of sickness, by analyzing into causes of morbidity the particular disease contributing to excess can be detected and the direction pointed out to ameliorative research. Morbidity shows its effect much more rapidly and is preferable as a guide.

1. The Statistics of Industrial Morbidity—A Retrospect and a Scheme for Development by R. E. Risher, F.J.A., *Jour. of the Royal Statistical Society*, January, 1922.

Although the occupation is the chief factor in sickness affecting the community as a whole, nevertheless there is little available information regarding male lives and none concerning female lives. Inquiries are inadequate without statistical knowledge of the incidence of sickness for the particular industry involved. Mortality takes too long to register to be effective as a guide to health work and is misleading, inasmuch as it records only the terminal condition and the occupation at the time of death. With the present trend of occupational disease to become compensable, it behooves each industry to make specific studies as to its morbidity rates and industrial medicine to evolve a comprehensive industrial toxicology based upon the precise analysis of existing conditions.

---

### Epidemiological Conditions in Eastern Europe

AMONG the first concrete fruits of the organization of the health section of the League of Nations we may welcome Number 1 of *Epidemiological Intelligence*, a bulletin to be issued in the future by the health section of the League as important material accumulates bearing on international health. The present number is of peculiar interest and importance since it gives us our first clear picture of health conditions in Soviet Russia. The tables and diagrams for the most part cover the year from September, 1920, to October, 1921, inclusive, and give us by districts the reported cases of typhus and relapsing fevers, dysentery, cholera, typhoid and scurvy in Finland, Latvia, Lithuania, Poland, Russia, Czechoslovakia, Austria, Germany, and Constantinople. These tables are supplemented by striking charts and diagrams and by a special study of the statistics of disease in the Red army which are of course much more complete than those for the civilian population as a whole. The case reports for most of the countries considered are obviously far below the true figure but they indicate very clearly the general cyclic changes which have taken place. Typhus reached a very high peak both in Russia and in Poland in the winter and early spring of 1920 and fell to a relatively low value in 1921. During the past few months, however, an alarming increase has been manifest in the northeastern and northern governments of Russia while a temporary breakdown of the sanitary cordon between Poland and Russia led to a material increase of typhus even in Warsaw during last December and January. The Polish government and the epidemic commission of the League of Nations are now apparently in control of the situation so far as Poland is concerned

but it is obvious that the post-war ravages of epidemic disease in Russia are by no means over.

The prompt distribution of statistical material of the sort which is contained in this first number of *Epidemiological Intelligence* will be of incalculable value to the sanitary authorities of the world.<sup>1</sup>

### Charitable Institutions Liable for Negligence

WE ARE convinced that "sound reasons sustain the great weight of authority to the effect that a public charity should not be held liable for the negligence of the servant in whose selection the hospital and its managers have exercised due care. On the other hand, such an institution is liable when it fails to exercise such care."

In these words the Supreme Court of Ohio upheld a verdict against a public charitable hospital for damages caused by an incompetent nurse. The decision is not a new one in American courts but it is one of the most unequivocal declarations yet made limiting the exemption from liability of charitable hospitals. The courts of New York, Texas, Washington, Rhode Island, Kentucky, Maine, and New Hampshire had held similarly that "the general principle protecting charitable institutions from actions for negligence does not include negligence that results in the service of incompetent, unskilled, or careless servants."

On the other hand the courts of Massachusetts, Missouri, Pennsylvania, Tennessee, South Carolina, Michigan, and Illinois, have upheld the view that charitable institutions are exempt from liability for negligence. The Massachusetts Supreme Court went so far as to say that "a public charitable hospital is not liable for negligence of its managers in selecting incompetent subordinate agents, any more than it is for the negligence of subordinates selected with care." The conclusion of most of the courts favoring the view is stated thus: "When a public corporation has no property or funds but what have been contributed for a special charitable purpose, it would be against all law and all equity to apply the trust funds thus contributed to compensate injuries inflicted by the negligence of its agents and servants."

Sweeping aside the above doctrine and also the doctrine that patients who accept the care of the hospital waive the right to damages for negligence, the court declares, "It (the hospital!) cannot watch or control the countless acts and movements of its servants, but it can and should exer-

cise care to see that only careful and competent servants minister to stricken patients who are within its walls."

Moreover, while it may well be said that donors of funds for the praiseworthy objects of charitable hospitals do not contemplate the diversion of the funds for the payment of damages for the numerous acts of servants referred to, yet they necessarily realize and appreciate that they give their donations to those who have the management and control of the institution, and that every principle of justice requires that they use care in the development and maintenance of the property and in the selection of servants who have the oversight of patients." The court further quotes approvingly from a North Carolina case where it is said: "The beneficiaries of charitable institutions are the poor who have very little opportunity for selection and it is the purpose of the founders to give to them skillful and humane treatment. If they are permitted to employ those who are incompetent and unskilled, funds bestowed for benefits are diverted from their true purpose and under the form of a charity they become a menace to those for whose benefit they are established.

The decision in Ohio may be overruled as to the particular case upon rehearing; the legislature may specifically exempt charitable institutions from all liability, which is an extremely doubtful possibility; the courts of other states may follow the view of non-liability held in Massachusetts, instead of the view in this case. But in the meantime the decision gives ground for speculation as to its effect.

The decision obviously has a direct and practical importance for those who administer charitable institutions. The decision fixes responsibility upon the governing boards of such institutions to exercise due care in the selection of these superintendents and assistants. Reasonable care in the selection of assistants is all that is required. Will it not be likely to cause trustees to take a more active interest in the institutions they govern? Will it not require a greater knowledge of standards in the management of such institutions?

### After Many Years the Philosopher's Skull Returns

THOSE who have read and pondered over the wisdom of the *Religio Medici* will be glad to know that the author's skull has rejoined the other remnants of his anatomy at St. Peter's Mancroft Church, Norwich, England, where they have lain since 1682. The story of the kidnapping in 1840 of this philosophic cranium and its

1. This and other publications of the health section of the League of Nations can be obtained through the World Peace Foundation, 40 Mount Vernon St., Boston.

final restoration to its first resting place in 1922, is not without its romance and touch of humor. Sir Thomas Browne, the original owner of the skull, was one of Norwich's most famous citizens. In some way his grave was opened and the skull stolen in 1840 and a few years later it found its way into the museum of the Norfolk and Norwich Hospital, where until recently it has been a highly prized relic. The vicar and church wardens of St. Peter's Mancroft, after eighty years of patient endeavor, have reached a friendly agreement with the hospital authorities who resolved at their last quarterly meeting, "That the skull shall be handed over to the church, on condition that it shall be reverently re-interred as soon as possible in the church near the supposed site of Sir Thomas Browne's grave, with the burying place suitably marked, and that before the skull is handed over a plaster cast of it shall be presented to the hospital authorities, and that it shall not be exposed in any way to the public as a relic of Sir Thomas Browne."

Rest noble bones collected here,  
 You lost your head for many a year.  
 A quaint philosopher of renown,  
 A doctor he, Sir Thomas Browne.  
 He's not the last, it may be said,  
 To lose his philosophic head.  
 But he's the first, I still maintain,  
 To get his brain-box back again.

---

### Medical Education, Licensure, Public Health, and Hospitals

A STEP was taken toward better understanding, even if unity of opinion was not achieved at the recent Congress on Medical Education, Licensure, Public Health, and Hospitals in Chicago. There was a serious stock-taking of the years work and a definite statement made of the immediate problems confronting the medical profession. Granted that we have on the one hand a highly trained body of physicians and, on the other, many communities indifferently served, responsibility attaches to both sides. A community short of service must assume the onus of providing the physical equipment of laboratory and hospital which will make it possible to carry scientific medicine to the outposts. Iowa has evolved an effective scheme of community hospitals, a plan that has been commended in New York. Such local centers have everywhere proved the basis for radiating activities directed toward the conservation of human health. The people also were conceded to be the logical participants in plans for better education. Superstitious and unscientific cults thrive where the people are ignorant. Even exact science is distrusted under

such a condition and no scheme of medical education is adequate that does not provide for popular education and popular support.

Inasmuch as the success of any enterprise depends first upon leadership in men, and second upon the cause itself, all medical men should have broader educational facilities and picked men should have special training. Particularly hampering is the lack of men qualified to act in the capacity of administrators. We have outgrown the system that trains physicians in the care of the individual patient, but does not fit them to handle community problems. The medical education of the future would better include the fundamentals of economics, civics, and the social sciences and some means provided to overcome the almost complete lack of facilities for training executives.

In the period of reorganization the physicians will lead if they are leaders, for reorganization means opportunity. It is a question not so much of methods as of men. It does not so much matter whether the Iowa plan of the community hospital as the center, the Ohio plan of making the physician felt through regional conferences, or the Alabama plan of constituting the state medical society the state public health association is followed, if ample educational facilities are provided for the people and the medical profession—fully alive to the people's needs—is on the job. It is a reciprocal relation.

---

PROVISIONAL estimates of the infant mortality rate in fifty-one cities on the basis of the estimated births for 1921 indicate a record low rate throughout the country, the extreme low rate of 47 per thousand being achieved by three cities,—Portland, Ore., St. Paul and Seattle,—the highest rate being 111 at Fall River, Mass. The outstanding lesson from a consideration of the falling rates is the uniformity of response to intensive health programs, again giving proof that to a large degree a city can fix its own death rate.

---

WITH the completion of Volume II the *International Journal of Public Health* suspends publication, its place being taken by *The World's Health*, the Bulletin of the League of Red Cross Societies under a new cover and a new name. The first issue of *The World's Health* offers as its leading article "The History of the Red Cross," by Georges Milsom. An account is given of the second meeting of the General Council of the League of Red Cross Societies and pertinent information is included on world health conditions.

## Advantages of a Model Industrial Cafeteria

Over Six Thousand Served Daily  
Table d'Hote Luncheon Gratis

BY LEE K. FRANKEL, PH.D., THIRD VICE-PRESIDENT, METROPOLITAN LIFE INSURANCE COMPANY, NEW YORK CITY

THE proper feeding of the world hinges upon the solution of two problems, production and distribution. When men have learned the secret of adequate production and of uniform distribution this problem will cease to vex their minds. Fortunately for the reader as well as the writer this article does not attempt to offer a solution of this tremendous problem. It only seeks to explain the solution arrived at by the Metropolitan Life Insurance Company of New York City as applied to its Home Office employees, comparatively few in numbers yet numerous enough to populate a town with more than six thousand men and women. It is true that this company faces only half the problem, for the matter of production is eliminated. Its problem is, however, sufficiently complicated to demand a high degree of executive ability and thorough training in things pertaining to a thoroughly modern commissary.

During the Great War the Metropolitan Life Insurance Company was brought face to face with the depleted labor market. It was found impossible to man the kitchen and dining-rooms adequately. The help which could be obtained was very mediocre as well as very scarce. In self-defense a cafeteria system was inaugurated. It is this cafeteria system which this article is interested in exploiting for it has proved to be as satisfactory as it is economical, and other large business organizations

may find in it the solution of their own problem of feeding a large number within limited time and in a limited space.

That it has proved economical both in time and money should not be surprising as the modern cafeteria is the latest development in the service of a quick meal at minimum cost to both management and patron. But this method of feeding is not as simple as it appears to the patron who is apt to think it the least complicated and

easiest method of serving food. In reality it is a very complex problem, especially when the cafeteria is an industrial one offering a midday meal without charge to so large a body of employees as are housed in the home office of the Metropolitan. The problem is still further complicated when the meal is a complete table d'hote luncheon such as this company serves.

It will be recognized at once that to feed more than six thousand persons within the short period of two hours is

Corner of kitchen of Metropolitan Life cafeteria. A pastry cook and baker are responsible for the baking of all breads and pastry and the making of all ice cream.

no small task. They must be fed rapidly but without haste. They must be served simply but with extreme neatness. They must be served in limited space, but without crowding. Each meal must provide a well balanced, ample ration, but there must be no waste through over-provision. To these problems must be added those presented by the cost of food, service, equipment, fuel, and light. All in all it is a task that only a clever, experienced, and specially trained mind can handle successfully.

To accomplish this without confusion, hurry, or waste the Cafeteria Department of the Commissary Division is divided into nine units or serving counters, the luncheon time is divided into three periods of thirty minutes each, and the office force is separated into nine groups of 250 employees each. For the sake of organization a unit is accounted to comprise one serving counter plus that section of the dining-room taking care of the number of seatings apportioned to employees assigned to that particular counter. Each of these units is assigned three lunch periods designated A, B, and C, corresponding to 11:45 a.m., 12:30 p.m., and 1:15 p.m. To each of these lunch periods is apportioned a group of 250 employees. This arrangement permits each unit to serve 750 individuals daily, and the nine units to serve 6,750 individuals daily.

In the ordinary commercial cafeteria much time is spent in searching counters to learn what the management offers. The Metropolitan saves this waste by displaying a menu on placards in easily read type. The menu is divided into sections lettered A, B, C, D, E. Each section of the menu is a properly slotted panel into which black cardboard strips are slipped. The items of food are printed on these slips in clear, white letters. Upon A are listed all hot and cold dishes, except soups. B is reserved for vegetables. C contains the soups. D is used for desserts. On E is listed the beverages, tea, coffee, milk, cocoa. Each of these sections is placed in plain sight over the counter from which the items upon it are served, and indicates whether one or more choices are allowed. So that employes may make no mistakes, intentionally or otherwise, as to the unit and lunch period to which they have been assigned, each of them is supplied with a ticket on which is stamped the unit and lunch period which the holder must attend. This assures each unit against overcrowding. These tickets are

By staggering the hours of eating, the cafeteria is enabled to serve 6,750 individuals daily between the hours of 11:45 a. m. and 1:15 p. m.

signed by the employees and must be presented to receive a meal. Should one be lost or forgotten application must be made at the ticket desk for an emergency ticket. Exceptions are only granted after consultation at the ticket desk.

All trays are inspected as the employes leave the serving counters. This was found to be necessary to preclude the possibility of an employe trying to make a meal of ice cream and dessert only. The empty dishes are left on the tables to be removed by table-cleaners.

This method has evolved an orderly, rapid service, but it is not as simple as the telling suggests. It runs smoothly and efficiently only because there is behind it a carefully planned and minutely carried out system extending from the manager's office, through the several departments, into the dining-rooms. It is not unlike a series of cog-wheels which pass an impulse from one to the other in orderly procession. A mishap to one involves the whole system in confusion and causes it to function badly. To avoid this the various assistants and sub-assistants have been selected with special care as to their fitness for the task committed to them.

Tracing the series backward, which means beginning at the serving-counters, we find five table-cleaners. These women remove the used dishes and trays and carry them to the washroom. At each counter are five counter-women who attend to the

actual serving. Over these ten women is a captain who is responsible to a head-waitress for the proper functioning of the unit over which she presides and the checking up of the items received. The head-waitress, who has the supervision of all the units, must see that the captains, counter-women and table-women perform their duties, and that each unit has its full quota of food, dishes, and silver.

The hot foods are brought to each unit by an especially assigned cook who supervises the proper distribution of this food into portions. The ice cream is cut and served by a baker, each unit having one baker for this task. The distribution of pies, pastries, bread, ice and beverages is in charge of a superintendent of pantries and dishwashing. This man is responsible for the daily supply of these items for each unit, as well as the supervision of the washing of dishes. His assistants use the morning hours, when there is no washing, for cutting bread, pies and cakes, for distributing them and the beverages, and for any other general work necessary for furnishing everything required by the units, excepting food articles from the kitchen.

We have now worked back to the kitchen where all the food is prepared and cooked. An experienced chef presides over the kitchen. He supervises the preparation and cooking of the food and its distribution into proper quotas for each unit in

accordance with requisitions issued by the manager. One of his assistants, known as chief pastry cook and baker, is responsible for the baking of all breads and pastry and the making of all ice cream. This includes the preparation and distribution of these articles. It is unnecessary to state that all the equipment of the kitchen and washing room is of the most modern type and kept in the most sanitary condition.

Given a certain menu to prepare and the raw material in proper quantities it is a comparatively simple process to turn out palatable dishes. The real problem, after the system of service and distribution has been chosen and organized, is the calculation of the amount of food items needed to meet the demand. This must be done so accurately that there will be neither an oversupply nor an undersupply. The Metropolitan solves this really perplexing problem by means of a carefully kept system of stock bookkeeping, the records of which run back for about twelve years. A secretary-stenographer keeps the books of this system. In them is recorded each day the number of meals served, the proportion of each item on the daily menus, the number of portions of each kind of food on the menus required by each unit, and the prices of every item purchased. From these records is calculated each day for the following day the amount of the various food items necessary to provide the luncheon for the number of individuals expected.

The make-up of the menus devolves upon a trained dietitian whose chief duty is to provide a balanced ration. This is subject to approval by the manager. The dietitian also controls all details of the menus and is charged with seeing that the food is served in an appetizing manner.

A unique feature of this cafeteria is the store-room bookkeeping. This comprises a stock-sheet for every article purchased and carried in stock. The sheet is so ruled that entries of receipts and issues to the different sections of the Commissary Division can be so made that a monthly balance is easily and readily obtainable. These records make it possible to ascertain the consumption of all sorts of food stuffs for the purpose of calculating the costs per capita. A similar sheet is kept for silver, linen, glass, and china.

The directing and controlling agency of this complicated machinery is the manager. He buys all supplies, sanctions all changes, and is

responsible to the President of the company for the efficient and economic conduct of the Commissary Division.

And what are the advantages of this cafeteria system over the older table-service? For one thing it saves money. Under the table service system the weekly payroll of two units totaled \$384, whereas under the cafeteria system it is only \$296. This is a saving of \$88 per week, or \$4,576 per year. The cost of installing the two first units was seven thousand dollars. In other words, each of these two cafeteria units paid for its installation in one year out of the difference in cost over the old system. As there is less handling of china there is an attendant saving in breakage amounting to almost 50 per cent. A considerable saving in food wastage has also been noted, owing in part to the fact that employees take only what they wish from the counters.

Added to these opportunities for saving is the fact that the food reaches the employees in better condition. Being served from heated receptacles directly to the patron it is hotter, there are less chances for the entrance of dirt, and it can be served much more neatly and in much quicker time, all of which makes the food more appetizing and therefore more nourishing.

In conclusion, it must be said that this system of cafeteria service is applicable only to an industrial cafeteria where a table d'hote luncheon is served without charge to the employees. For this type of cafeteria it is efficient, economical, and satisfactory to both management and employees, which in the last analysis is the real test.

### New Jersey Medical Society Welfare Work

A Welfare Committee has been appointed by the president of the New Jersey Medical Society, a part of whose activities have to do with legislation to require a single standard of qualifications for all who seek unlimited privileges to practice healing arts. There is also the intention to seek an amendment to the Workmen's Compensation Law, which would provide for what physicians think would be a fair compensation for both the hospital and the physician in the care of persons injured in industry.

It was decided to ask the State Board of Institutions to place a physician on the board of managers of the various state institutions in which the care of the health of the inmates is a large factor. The Committee also recommended that a physician be placed in an executive position on the State Rehabilitation Commission.

### Air Tank Relieves Paralysis

International.  
The Brooklyn Navy Yard maintains as part of its equipment a compressed air tank in which divers suffering from "caisson disease" caused by working under water are returned to their normal condition. The paralysis is caused by the necessity of breathing compressed air which results in too much nitrogen being taken into the body. This forms bubbles which break only when the sufferer is again subjected to compressed air. The picture shows Torres Olson, a diver, whose paralysis disappeared upon being consigned to the compressed air tank.

# Oil Camp Sanitation in the Southwest\*

## Proper Living Conditions Will Decrease Camp Labor Turnover

By C. P. BOWIE, PETROLEUM ENGINEER, U. S. BUREAU OF MINES, WASHINGTON, D. C.

IT is a regrettable fact that very few of the employers of labor in rural districts in the United States ever seem to consider the value to their enterprises of maintaining sanitary livable camps for the men in their employ. This seems to apply especially to the oil operators of our mid-continent fields.

One need only to visit almost any of the oil communities of Texas, Oklahoma, Louisiana, or Kansas, now passing through the "boom" stage, to be impressed by the necessity of more and constant work on the part of Federal and State bureaus, as well as on the part of the operators themselves, to the end that the deplorable living conditions in some of these districts, so far as public health is concerned, may be improved.

Many oil men, operating in districts east of the Rocky Mountains, employ the contract system of drilling the wells, which almost precludes the possibility of the companies building up camps or small towns over which they may exercise personal supervision as to housing and sanitation. That is to say, the companies bargain for the development of their properties with a contractor who furnishes all the materials and labor necessary to the drilling of the wells and work appurtenant thereto for a stipulated price, thereby relieving themselves of all responsibility other than their financial obligations to the contractor.

As a result of this system, the contractor hires his drillers, tool dressers, and laborers, how and where he can. Most of them are brought in from outside districts and if oil is "struck" and the field gives promise of commercial production the oil workers are followed by freighters, "jitney" drivers, restaurant keepers, inn-keepers and the innumerable small trades-people who, with their families, go to make up the population

*The insanitation of oil camps is often excused by the statement that conditions are not "normal," that when the community has become established and oil is "struck," a sanitary system will be installed. Such an excuse has proved costly, and fires and epidemics have followed in the wake of such reasoning.*

*The wise employer knows that by maintaining the health of his workers and bettering their standard of living he has nothing to lose. Statistics show that the time saved from illness by good sanitary measures far exceeds the expenditure for sanitation. To locate the camp on high dry land with proper drainage, to insure a safe water supply, to install an adequate sewage and waste disposal system are the three main factors in camp sanitation.*

of such districts. So it is that a trackless prairie sometimes becomes almost overnight the center of a community often numbering thousands of people who establish themselves in temporary buildings, tents, dugouts, lean-to shelters, and even within four topless walls of burlap, or in the

open. These mushroom communities have been aptly termed "rag-towns".

### Insanitation of "Rag-towns"

They have no water supply or a wholly inadequate one; garbage, decaying vegetable matter, tin cans, old rags, and paper, lie in small heaps about the temporary structures or are strewn promiscuously over the vacant places. For sewage disposal privies are built. Some of these are made from new lumber with rain-proof sides and roofs, hinged doors, and battens over the cracks. However, many are makeshifts, consisting of old boards on end, teepee fashion, or sacking hung on a frame about an improvised seat over a shallow hole, with no pretense of screening out the flies or affording protection from vermin. Practically all of these structures, the ones especially built for the purpose as well as the improvised ones are, except perhaps in the coldest days of winter, swarming with flies, reeking with filth, emitting noisome odors, and altogether so disgusting that the populace refuses to use them. The result is that privacy is sought under cover of darkness and the ground for acres about is defiled.

It is argued that while these facts are deplorable, they are the results of unusual circumstances and that matters will be remedied as soon as

Plate I. General layout of Pacific Oil Company Camp in Elk Hills District, Kern County, California. This camp illustrates what can be done at relative small cost for the welfare of the men.

Plate II. Dining room, showing neat appearance of tables and open gas heater in corner.

conditions return to normal. But experience has shown that the so-called "normal" conditions never return before the community has been visited by a series of costly fires and epidemics. In fact, generally "normal" conditions do not return until the field has been proved a success or a failure, and this often takes months or years.

The responsibility for the betterment of such conditions is plainly up to the state governments. Broadly speaking, all states have legislation sufficient to cope with these exigencies, but the fault lies in the enforcement of the laws. This too often is left to the immediate community itself and rests in the hands of a few men who, because of their political aspirations, cannot afford by the enforcement of ordinances to run the risk of antagonizing their neighbors, or who are so engrossed in money gathering that they are indifferent to the responsibilities entrusted to them. Therefore, the refusal or neglect of someone to meet the social responsibilities which come with the hiring of human beings for labor brings hardship and unnecessary misery to a class of people (especially to the women and children) who are unable or indisposed to combat personal indignities which make for degradation, crime, and the social unrest already burning in uncared-for migratory workers the world over.

While society does not place the responsibility for these deplorable conditions upon the employer, nevertheless he is also a sufferer. If he would but stop to consider, surely he must see a material loss to his enterprise through "soldiering" discontented workers, petty strikes, and a force

continually quitting. The oil operator who through his daring enterprise is adding so much to the wealth and prosperity of our nation should remember that after all it is through his leadership that human beings congregate in our oil fields and that with that leadership, morally at least, there goes also a measure of responsibility for the lives and happiness of these of his fellow beings. He can do much to add to their welfare and at the same time bring increasing prosperity to himself.

#### Flies as Disease Carriers

Experience has shown that insanitary conditions will often result in a 25 per cent loss of working efficiency among the men. Suppose a camp of fifty men with an average daily wage of \$5. A 25 per cent loss in efficiency would mean a daily loss of \$62.50, or \$1,875 a month. One roustabout at, say four dollars a day, would serve to keep the camp clean after it was once put in good condition; and an additional expenditure of \$6 a day should provide necessary teams, extra labor, and repairs, so that \$300 a month would cover the cost of good sanitation and the actual saving would be \$1,575 per month, or \$18,900 a year. From the first year's saving it would, of course, be necessary to deduct the initial cost of the various sanitary installations, but this for a camp of fifty men should at most not exceed \$3,000.

Flies are the greatest of all disease carriers. They breed in manure piles, kitchen refuse, and human excrement. They are very often directly responsible for the spread of such diseases as typhoid, dysentery, diarrhea, and other intestinal disorders. If you dispose of the breeding places

of the flies you dispose of the flies, thereby doing away with one of the main causes of camp sickness. This can be largely accomplished by proper disposal of the manure, garbage, and sewage. The flies that come into the camp from outside and sometimes relatively remote places where their breeding places are allowed to remain undisturbed may be captured in suitably constructed traps. A very efficient trap is described in Form 45-C of the Department of Health, Commonwealth of Pennsylvania. Sticky fly paper is also a convenient and effective means of disposing of these "stray" flies.

Some varieties of mosquitoes are carriers of disease such as malaria and yellow fever. Mosquitoes breed in stagnant, preferably dirty, pools. The females of some varieties lay eggs one at a time, others as many as three hundred, which float on the surface of the water in the form of a raft. In about two days, depending on the temperature, the eggs will hatch into larvae or "wrigglers" seen so frequently in rain barrels. The larvae must have water to live in, also they must have air. This they breathe through a tube a little to one side of one extremity.

Larvae can be destroyed by draining the places where water collects. Old tin cans, bottles, or any waste vessels that will hold water should be removed or destroyed. Tubs and barrels used for the storage of water for domestic purposes should be kept covered. Holes in tree stumps, roadside puddles, and depressions in rocks, should be kept free from grass and marshes should be drained. If the stagnant pools are too large or it is not practical to drain them, then they should be sprayed at frequent intervals with kerosene or crude oil. The oil forms a scum on the surface of the water through which the tube of the larvae cannot penetrate. They, therefore, die for lack of air. Large ponds may be stocked with fish, as fish feed on the larvae.

#### Location of Camps Important

A camp should be on well drained ground. This rule is important and must be followed even though the men walk a short distance to and from work. The living quarters, kitchen, and commissary houses should invariably be on the higher ground. Under no circumstances should surface drainage be from the corrals, stables, and chicken pens toward the living quarters. If the camp has promise of being even semi-permanent, careful thought should be

Plate III. Range and serving table in kitchen at Elk Hills camp. The hood above the range carries off smoke and odors.

given to its layout. It will pay to survey the site and prepare a contour map upon which the proposed structures may be located with due consideration to drainage and prevailing winds.

If houses are to be built they should be comfortable, roomy, attractively painted inside and out, and conveniently arranged for housekeeping. In warm climates or in parts of the country where the summers are hot, they should be provided with verandas and screened porches. The grounds about them should be improved with lawns and trees. This does not mean that an undue amount of money must be spent on such structures. A house that is conveniently arranged for housekeeping can usually be as cheaply built as one that is not; thorough painting preserves the wood and greatly lengthens its period of usefulness; lawns, flowers and trees yield dividends in contented workers, avoiding the losses by constant turnover in forces.

A good example of what can be done, at relatively small expense, looking toward the welfare of men employed in oil work is demonstrated in the accompanying illustrations<sup>2</sup>, showing a recently constructed oil camp in Kern County, California. This camp is about twelve miles from Taft, in what is known as the Elk Hills district. This is an arid region having short temperate winters and long hot summers. Plate I shows the general layout of the camp. The buildings, being on the tops of the hills, afford ideal drainage conditions during the winter rains and a maximum amount of breeze in the summer time. The plate also gives a good idea of the screened porches. Guards

protecting young trees may be seen in the foreground. Plate II shows a portion of the dining room in which may be noted the neat appearance of the tables and the open gas grate in the corner. Plate III shows the range and serving table in the kitchen and the hood above the range for carrying off the smoke and odors. Plate IV shows a refrigerating machine used to keep the food cool during the summer months. Plate V shows the garbage incinerator. One of the buildings at this camp is an up-to-date change room, fitted with lavatories, shower, and tub baths supplied at all times with hot and cold water.

#### Well Guarded Water Supply

A plentiful supply of pure water for domestic use is very important. If the source of supply is a spring, it should be housed in and carefully guarded against possible contamination. Cesspools or privy vaults should be so placed that pollution of the water supply is impossible. If a stream is the source of supply it should be protected from cattle and stock by fencing for a reasonable distance above the intake, and the intake should be carefully screened and cleaned as often as necessary to keep the water free from organic contamination. Wells, if used, should be protected against surface drainage and the same precaution as for springs should be taken against cesspools and privy vaults.

At temporary camps, garbage may be disposed of by burying it in the ground, but at permanent camps it should be disposed of either by burning or feeding to hogs. It should not be fed to chickens, as chickens will not consume such things as the peel-

ings of most vegetables and coffee grounds, and these will afford breeding and feeding places for flies. If fed to hogs, the hogs should not be allowed to roam about the camps, but should be kept in pens which are kept clean, otherwise they also become a breeding and feeding place for flies, as even hogs will not consume coffee grounds and some varieties of melon rinds.

#### Sewage and Refuse Disposal

Manure piles are the favorite breeding places for flies. They should not be allowed to accumulate. Stables, when in use, should be thoroughly cleaned daily and the manure either hauled into the field and spread in thin layers on the land, placed in properly constructed compost pits,<sup>3</sup> or burned.

If manure is spread in thin layers in the field not to exceed one inch in depth, owing to rapid desiccation it soon ceases to be attractive to flies. The heat of the sun will kill the eggs and the larvae in a short time. Where it is not practical to dispose of manure promptly, fly breeding may be prevented by sprinkling it with a solution of hellebore. About one gallon of the solution should be used to every cubic foot of manure. Such treatment will destroy 99 per cent of all fly larvae present and the treated manure is not poisonous to chickens, neither is its value as a fertilizer impaired.

There is probably no one subject upon which sanitary engineers are more thoroughly in accord than the inherent vileness and danger, even under favorable conditions, of the open privy closet and cesspool as ordinarily constructed. Fresh sewage is not always injurious to health, nor is its odor usually very offensive, but putrefying excreta and kitchen slops, especially during hot weather, are not only most disgusting to sight and smell, but become breeding places of myriads of flies, which, as pointed out before, carry disease germs to be deposited on the food eaten by the workmen and their families.

Where camps are of a very temporary nature lasting not more than a few months, the privy type of toilet is permissible, but, as already stated, it must be kept at all times sanitary, and both the pit and the housing should be made and kept fly-proof. All openings, including knot holes, should be screened and cracks between boards should be carefully battened. The bottom of the housing must be banked with earth so that there will be no opening between the

Plate IV. The camp maintains a refrigerating machine for cooling food during the summer months.

bottom sill and the ground. The doors should have spring hinges, coils, or some other arrangement that will insure their closing automatically. As an added precaution, each seat should be provided with a cover arranged to drop automatically over the hole, and the surface of the excreta should be kept well covered with crude oil or lime. The pit should never be less than five feet deep and when it is half filled a new pit should be dug and the building moved over it; the old pit should be first burned out, then filled with earth. Such a system of sewage disposal can in no case be recommended for permanent adoption and can be used with safety only when constant vigilance keeps the buildings fly proof.

In the past it has been the practice at permanent camps and in many cities and towns to convey sewage by a water-carriage system into a cesspool. Because the cesspool was covered up and so far from the buildings that the noisome gases did not become a nuisance, it was supposed that the sewage was being disposed of properly.

Undoubtedly there are places where this system properly disposes of the sewage, but in the author's opinion such places are the exception, as the successful operation of a cesspool depends on septic action. To insure septic action, the surface of the water in the pool should remain at practically a constant height; that is, the water should seep into the soil at the same rate it enters the pool. This,

of course, is seldom possible. On wash days, for example, there may be an influx of water that will almost fill the cesspool. When the water recedes, the scum of bacteria and excreta on the surface will stick to the walls of the excavation, and if the cesspool is not properly covered it will, like the open privy, afford a breeding place for flies. When the sewer system is not in use for a time, as may happen if the buildings are vacant, all the water may seep out of the cesspools and the scum of excreta and bacteria left behind may cover the bottom as well as the sides. Repeated occurrences of this kind may so affect the porosity of the soil that the water will cease to percolate through it, with the result that the pool overflows and becomes a positive danger to everyone living in the vicinity. Any type of sewage disposal that does not preclude the possibility of flies coming in contact with the excreta or other waste material is unsatisfactory.

A septic tank is simply a nonleaching (water-tight) cesspool provided with an overflow and is not necessarily, as is generally believed, a complicated and costly structure dependent on careful attention for satisfactory results. Its construction is comparatively simple. The septic tank is well adapted for use in almost any part of the United States and costs only a little more than the ordinary cesspool.

The purpose of the septic tank is to separate and settle from the liquid as much as possible of the solid material in the excreta and to destroy the solid material by bacterial agencies. Part of the material will settle in a short time, part will remain in suspension for a long time, and some is so finely divided that trying to settle it out probably would be impracticable. The theory of operation is that the solid matter is attacked by countless bacteria, which change most of it into compounds that are liquid or gaseous. Some of the solids rise and form a scum over the surface of the liquid, whereas others sink to the bottom of the tank. As this scum excludes the light and air and may be regarded as an aid to septic action, it is desirable that it should remain undisturbed except when the tank has to be cleaned.

The essential points about a septic tank are: (1) That it be water-tight; (2) That the compartment receiving the sewage be so arranged that the water from the sewer mains may pass through it without appreciably disturbing the surface. These

Plate V. A garbage incinerator takes care of the kitchen waste.

tanks are of different forms, some more or less elaborate having automatic siphon discharges. However, they can be simply constructed at relatively small cost and still give thoroughly satisfactory results. The writer knows of no tank that, considering first cost of construction, convenience, efficiency, ease of maintenance and the like, gives better satisfaction than that described in U. S. Bureau of Mines Technical Paper 261, entitled "Oil-Camp Sanitation."

### Inefficiency Due Largely to Imperfect Sight

The Eye Sight Conservation Council is responsible for the statement that in a careful examination of ten thousand industrial and commercial workers, active in their work and supposedly in good condition, fifty-three per cent showed defective vision uncorrected. It is an absolute fact that many employees are accused of inefficiency and carelessness when it is entirely a matter of imperfect vision.

The motion picture camera is made in imitation of the eye. The better the condition of the lens and the better the illumination of the object, the better the result of the photographers effort. Just so with the more perfect instrument, the eye. It behooves every one to see that his eyes are kept in good condition and free from eyestrain coming from defects which may be corrected by glasses, or the strain due to improper lighting.

# Occupational Influences in Tuberculosis Rates

## Education of Workmen Important Factor in Combating this Disease

BY I. A. GALDSTON, M.D., SECRETARY INDUSTRIAL SERVICE, NEW YORK TUBERCULOSIS ASSOCIATION, NEW YORK CITY

IN THE *Monthly Bulletin* of the New York Tuberculosis Association for September-October, 1921, there is contained a brief statistical study made by G. J. Drolet, Chief Statistician of the Association. The story of the study, so tersely told, is of greatest importance to all interested in public health and especially to those who view it from the industrial angle. The results of the study prove that tuberculosis in New York City is primarily a man's disease, and that during the last ten years, with but slight variation, the mortality rate from tuberculosis for men has been, and is, twice as high as that for women.

In considering the results of this study two questions present themselves at once; the first is, what are the causes of this higher mortality among men, and secondly, what can be done to remedy this condition. In the attempt to answer the first question, that of the reason for these differences in mortality, one fact from among others presents itself as most salient. That fact is that in New York the percentage of men employed in gainful occupations as compared to that of women similarly employed is approximately 2½ to 1. Out of a total 2,531,637 persons engaged in New York in gainful occupations, 1,838,541 or 72.6 per cent are men and 693,096 or 27.4 per cent are women.

To appreciate fully the significance of this last point, one must view it in the light of our latest knowledge of the etiologic factors of tuberculosis, for here it is seen that great changes have taken place. For the earlier concept of the etiology of tuberculosis which dwelt with an almost blind exclusiveness upon the home environments has been substituted the broader one which, while not abandoning the factor of home environments, has focused attention upon all those factors which affect the bodily resistance and vitality of the individual. The modern concept of active tuberculosis is that it is an adult development of an early childhood infection, resulting primarily because of a lowered body-resistance.

J. W. Turner in "A Tuberculosis

*In the last ten years in New York City tuberculosis has been essentially a man's disease, the male mortality being twice as high as that for women. The reason for this is seen when one realizes that the great majority of trades which predispose to consumption are followed almost exclusively by men. Since conditions in industry are often the cause of the development of tuberculosis in the individual, the education formerly brought into the home and the school must now be taken to the workshop and factory, the office, the union meeting, and apprentice school. The economist and sociologist by efforts to shorten hours of work, to increase wages to a living standard, and to lighten the fatigue of hard labor can do much to reduce the mortality.*

Background for Advisers and Teachers," says:

Practically all the evidence at hand indicates that adults do not develop tuberculosis as a disease because of contact with tuberculous adults, but rather from a tuberculous infection received years before, most probably in childhood. The tubercle bacilli are walled off, they are hidden away and lost sight of, but at some crisis the tuberculous focus becomes permeable.

The same view is thus presented by the English authority, Cobbett, who states:

Tubercle bacilli are so commonly present in the air we breathe and in the food we consume that opportunities for acquiring infection come to all of us, and indeed most of us do actually become infected at some time or other during our lives. But the disease soon becomes arrested in the majority of people, and leaves only a little scar in the lung, or a calcareous focus in some gland.

Opportunities for infection being so very common, as these facts show them to be, it is manifest that they can count but little in the ultimate result. *The determining cause whether we develop some unimportant lesion or a progressive and fatal disease must therefore depend on some other factor, and that factor can only be the power of resistance possessed by the individual.*

If this last concept of the cause of the development of active tuberculosis be correct, and it is the consensus of medical opinion that it is so, it behooves us to ask what are the factors current in the daily life of the individual that most seriously threaten and are most competent to undermine his resistance and to sap his vitality. But little mental effort is necessary to realize that the industrial factors play just this rôle. For it may be said with no fear of any warranted contradiction that the hours the individual spends in the office, factory, shop, or mill, are the most strenuous and taxing of the twenty-four included in the day. In the work place the individual is not master of himself but only a conscious element in a complex industrial machine that requires the unconditional cooperation of all its various parts and elements. The machine drives the man, the ledger leads its keeper, and the business appointment drives the executive. Irrespective of the wishes or the demands of the physical being of the factory worker, office worker, or executive, they must each do as the industry demands or clog the work.

This situation is truly presented, and, while from the view point of national health it is a lamentable situation, it is incumbent upon us not to lament over it, but to realize it. And because industry is so very capable of and so liable to undermine individual resistance, and because there are so many more men than women at work in New York City, the causes for the marked difference in the mortality of men and women become quite evident. That this conclusion, as well as the discrepancy in male and female death rates from tuberculosis, holds true for other industrial centers than New York, can be seen from what Cobbett has to say in his study on the "Causes of Tuberculosis":

It can hardly be doubted that this difference depends in the main on differences of occupation, for the great majority of the trades which predispose to consumption, in England at least, as well as in the United States, are followed almost exclusively by men. This view of the case is supported by the fact that the

difference in the comparative liability of the two sexes to die of tuberculosis has increased greatly in modern times, that is to say *pari passu* with the continued growth of our industries.

Thus we can account for the chief causes of the high mortality rate from tuberculosis among men. But the causes being accounted for it now remains to give answer to the more important query as to what can be done to remedy the condition.

At the very outset perhaps it will not be amiss to say that in the opinion of the writer whose experience with workers and workers education has been extensive, relatively little can be done for the worker. This catagoric statement is made in order to impress upon the reader the fact that the situation does not demand the services of the philanthropist. It is not philanthropy but education that is required. Nothing needs to be or can be done for the worker beyond teaching him to do things for himself. Education is his primary need. For even though the most modern sanitary equipments be installed in the workplace and though the best equipped dispensaries be placed at his command with experts ready to serve him, nothing will avail if the worker is not first taught to appreciate the need for and the value of all these health guarding elements. What industrial physician has not seen wheel guards converted into receptacles for the workers tobacco and pipe, guard glasses worn in the hip pocket, and wash basins converted into paper baskets.

Even more concretely and to the point is the experience of the Union Health Center. Here is an institution representing approximately \$100,000 of the workers money invested in the construction and equipping of a model medical center, and yet despite the fact that it is all the workers' own institution, governed by his representatives in the interest of the Union, the number of men and women that take advantage of the health conservation facilities thus offered to them represents but the merest part of the total. In the face of such facts, what else but an intensive and extensive educational campaign can avail?

In thus stressing education, the writer is well aware that the education of the workers is no panacea. No amount of educating the workers, as such, will shorten the hours of work or increase wages to the living standard, or lighten the burden and fatigue of hard labor. Education as such can only ameliorate conditions

under the circumstances given. Those conditions of work, wages, and hours need to be changed, but the consideration of the same falls in the domain of the sociologist and economist rather than in that of the industrial physician. Suffice it in passing to say, however, that the writer well knows that both workers and employers need education.

Education is a vague expression to which we must give clear definition in order that it be properly understood. Though at first it may appear like a difficult task, in truth it proves otherwise. For education as a means of reducing morbidity and mortality is no new use made of learning. It is only the education of the worker in the shop, factory, and office, that is relatively new. For many years, education in the prevention of tuberculosis as well as in the hygiene of the tuberculous patient has been brought into the homes and schools, to the minds of the women at home and the children at school. Now we need to bring it into the factory, shop, office, union meeting, apprentice school, and wherever else the workers can be gathered into groups and made to listen and to learn. No doubt in this last educational effort the methods employed will differ from those formerly used in the home and school campaigns. The field is bigger and more complicated but we have greater facilities. We have the moving picture capable of silent but impressive lessons. We have its static brother the colored projection slide. Great masses of workers can be addressed during lunch periods, or if the employer is sufficiently enlightened, on the time of employers and employees in the forenoon or afternoon.

A scheme but little tried as yet is the circulating miniature exhibit made up of photographs affixed to a board with appropriate short description of the points they illustrate and suitable literature for the workers to take with them and read at their leisure. Such miniature exhibits take up but little space in the factory and can be made to circulate from one shop or factory to the other with excellent results. Evening classes in "health and tuberculosis prevention" in the adult state and union schools offer another very good means of reaching the workers, especially the younger ones whose minds are still plastic and open to impressions. The publication of health articles in trade papers written especially for the particular trade is also an effective educational activity.

All these various means, and what

ever others the genius of the industrial physician and health worker is sure to uncover when in close contact with the workers, if practiced long enough are sure to affect deeply the understanding and attitude of the workers and to produce an appreciable fall in the male mortality from tuberculosis. The rest will need to be done by the economist, the sociologist, and by the theoretician as well as by the practicing physician. By working together it may not be long before the Great White Plague is robbed of all its terror and its victims now counted in the millions may be reduced to but a relative few. At first, however, we must reach the worker as we have never reached him before, for as is proclaimed by the motto of the Union Health Center, "In matters of Health as in economics, the salvation of the workers depends upon the workers themselves."

### Protect Salt Lake City Water Supply

Installation of the police signal system from which Salt Lake City's water supply is drawn is proving an invaluable safeguard.

The water supply for the city of Salt Lake is from sources far above the city and is distributed by means of gravity; the reservoirs are some distance away from the city. Men have been on duty at all times at the reservoirs, but under the new system three shifts of men safeguard the reservoirs and intakes. It is their duty to keep campers at a safe distance from the streams and guard against the pollution of the water by horses, cattle, and sheep.

A signal system has also been employed for making reports. This system is proving invaluable in guarding against grass and forest fires.

### Health Service Lengthens Life Expectancy

The Statistical Bulletin of the Metropolitan Life Insurance Company offers as a convincing instance of the beneficial effect of a well considered campaign of health education figures on the mortality experience of the policyholders in their Industrial Department. The program now embraces more than thirteen million men, women, and children of the wage earning population of the United States. At the end of ten years the death rate has been reduced more than one-fifth. A total of 38,000 fewer deaths occurred in 1920 than if the 1911 rate had prevailed.

# The Medical Aspects of Personnel Work\*

BY ROBERT E. ANDREWS, M.D., LUDLOW MANUFACTURING ASSOCIATES, LUDLOW, MASS.

THE subject of this paper, that of the correlation of the medical and employment departments in industry, was chosen because of the many placement problems which have arisen in the course of the author's work as an industrial physician, and which could be properly solved only after conference and intimate discussion with the employment manager. Such conferences have been invaluable both in giving the examining physician an appreciation of the employment manager's viewpoint, and in giving the employment manager an insight into the medical aspects of the problems considered.

There are many functions in common between the two departments of employment and medicine in which the interests are essentially interlocked.

## The Job Requirements

Perhaps the most readily accepted function lies in the placement of a worker where best suited. This presupposes a careful job analysis and entire familiarity by the heads of both departments with the physical and mental requirements of the jobs to be filled. The data in the hands of the employment manager are not sufficient without additional data in regard to the fatigue element and the physical type best fitted after study by a qualified industrial physician. Different concerns have attempted to standardize a rating of incoming employes, and many have accepted the four groups developed by the Conference Board of Physicians in Industry. These are as follows:

(1) This group comprises those physically fit for *any* employment. This group is necessarily small, as few are found able to fill such a requirement.

(2) The next group is composed of those physically fit but below par in development or other conditions. The vast majority of employes come under this heading.

(3) A third group comprises those physically fit only for certain employment when specifically approved for it by the examining physician. Many cases range themselves under this heading.

(4) Then there is the group of those unfit for any employment. Such workers are relatively few, and comprise the rejection cases generally.

Members of the New England Con-

ference of Industrial Physicians have accepted this rating, but with the privilege of modifying it according to local conditions. For instance, in the textile industry employing the author, three main industrial hazards are recognized: Dust, dampness, and extra heavy manual labor. So the classification of an incoming employee's physical rating after examination has been divided into four classes to cover these hazards. (1) The first group comprises those fitted for the jobs for which they are to be hired. (2) The second group cannot be hired on a dusty job. This group comprises those with chronic throat affections, bronchitis, asthma, hay fever or history of old pleurisy or lung trouble. (3) The third group cannot be hired on a damp job because of a history of present or past rheumatism or neuralgic seizures. (4) The fourth group cannot be hired on a weight lifting job because of present or potential hernia, or high blood pressure.

Doubtful cases are discussed thoroughly with the employment manager before deciding to take them on as impaired workers. If given employment, there should be periodic check-up examinations at intervals, and always before transfer to another job. The author believes that a physical rating of new employes by a qualified industrial physician should be made whenever possible, and that the data from this will prove of inestimable value to the employment manager. As was first pointed out by the Conference Board of Physicians in Industry, by means of this rating three sources of danger are eliminated; first, the worker dangerous to himself through fits or fainting around moving machinery; secondly, the worker dangerous to others through contagion; and lastly the worker dangerous to property through mental unbalance.

Fainting spells and mild fits most of us have met with, the difficult cases being those who are unaware of recurring short lapses of consciousness. Further questioning usually brings forth the fact that they have bitten their tongues in their sleep which is one of the occasional effects of *petit mal* or mild epilepsy. The author has had some five or six suspected cases referred by the employment department in the past year alone.

Skin diseases, parasites, and to a

less extent, venereal disease are another source of danger to fellow workers, and require considerable judgment and not infrequent consultations in placement.

The out and out mental case, the paranoiac, with his delusions of being followed, spied upon, and threatened, is rather rare. But these cases do present themselves and should receive medical attention and observation in the plant. My last experience with such a man was in the case of a crane operator who claimed somebody was always watching him and talking about him, and had put something into the gears of the machinery. When he reported that he was being followed by the same party, we became suspicious and on examination by two alienists resulted in prompt commitment. The employment manager is, however, interviewed frequently by people who feel they are not getting a square deal at their jobs. These cases are a real problem and occasionally a slight mental aberration comes to light on observing their habits and studying their mental paths of reason. In all of the above classes of cases consultation and cooperation are very necessary functions of both the employment manager and the medical man.

## The Woman in Industry

The problem of the pregnant woman, the author realizes, is confined to relatively few industries, but plays a fairly large part in textiles. How large a part it plays with the concern with which the author is associated may be gained by the statement that more than 10 per cent of our "help left" during the year are obstetrical cases. When 10 per cent of your exits are from one cause, time can be well spent in investigating such cause, as contributing to labor turnover. The Commonwealth of Massachusetts limits the time these cases may work and the period of convalescence before re-employment, but the industrial physician is the employment manager's right hand in determining whether such cases are harming themselves and slowing production by being kept too long on the job, and also whether, as efficient workers, they are physically ready to return to the work, on appearing to seek again their old job.

One of our New England Textile

\*Read before the Springfield Employment Managers' Association, Springfield, Mass., February 7, 1922.

Industries is now completing an analysis and study of the pregnancy factor in their labor turnover. Last year they had 126 such cases, twenty of them illegitimate. The most frequent age was between twenty-five and thirty years, and the pregnancy was most frequent in those having worked four years in the mills. Over 50 per cent of these are without other dependent children. Women constitute about 60 per cent of the total employes in this plant, and while the work is largely unskilled, yet experienced help is usually in demand. The employment records of these women show rather frequent exits and hirings. The study of the reasons for this frequent turnover is not yet complete but analysis of the pregnancy cases by nationality shows that in a nearly even given number of cases of Portuguese and Polish women, the Portuguese women were hired on an average of three times in three years, while the Polish women averaged four times in eight years. In other words, in this particular textile plant the Polish women who became pregnant had worked proportionately twice as many years on the same number of hirings. While the number of these reported cases is too small for definite conclusions, yet it would seem from the above that a woman within the age limit of twenty-five to thirty years is more liable to increase the labor turnover through pregnancy, and that, other conditions being the same, a Portuguese woman is twice as liable as a Polish woman to do so.

### The Personal Element

A well recognized function of both medical and employment departments is that of bettering industrial relations. Almost daily, conferences are held in individual cases. Recently there was the case of a woman whose work had been reported to the Employment Department as deteriorating in quality. Investigation showed her to be doing the house work at home with the care of five children, and her husband unable to find work. Medical examination showed an anemic, debilitated, underfed woman, fatigued at the start of the day, and mentally discouraged. As a result of cooperative effort, her husband was given work, that she might remain at home to convalesce and follow the advice and treatment of the plant physician, whose personal interest, knowledge of her disadvantages and opportunity of advising and helping her, will go a long way in establishing a close human relationship with

the Employment Department. The true story is often first learned in the consulting room of the physician, and has not infrequently proved vital in the solution of the problem.

Harmful working conditions often first come to the notice of the Employment Department through physical complaints of workers consulting the physician. There are numerous dust hazards of varying degree in the textile industry. While generally organic in character, it is often an unrecognized source of respiratory irritation. In the textile industry employing the author, five cases were found to have been discharged from the job during the past year because of irregularity in attendance at their work. On checking up with the medical records, it was found that in each specific case the worker was subject to asthmatic attacks or chronic bronchitis brought on by dust irritation. The Employment Department was able to correct the manifestly unfair treatment of dropping these men from the payroll, by placing them at other work. The risks of the job were called to the management's attention and were corrected by installing dust removal apparatus.

Another problem which many employment managers have been called upon to solve is the consideration of the industrial cripple and the finding of work which he is fitted to do. The latest figures published by the Massachusetts Industrial Accident Board are for 1919. They show a sum of 78,000 lost time accidents for that year. Among these were 1,319 cases of partial disability lasting more than one year, and a total of 1,639 cases of partial disability with the loss of a member,—all of this in one year in Massachusetts alone. The figures for 1921, when published, should be proportionately greater. Yet to the writer's certain knowledge in his past two and one-half years of examining prospective employes, rejections for physical disability have run below one-half of one per cent. In other words, while pre-existing hernias average between 6 and 8 per cent of the men hired, heart complications about 2 per cent, and history of previous lung complications about 5 per cent, yet the Employment Department has been enabled to place the doubtful risks in occupations where they have become safely absorbed in the industry. This work was materially helped by conferences with the foremen, who reported as the result of a survey of their respective departments, what jobs in their judgment might be considered

available for temporary or permanently disabled workers.

The ability to keep at work an injured employe even at a minor temporary job means a real saving to him in dollars and cents in wages which he would otherwise have lost in waiting for compensation, means a noticeable reduction in absenteeism, and lowers the experience rating for lost time accidents, which in turn is reflected as a real saving in dollars and cents to the management in reduction of the insurance premium.

### The Child Laborer

The problem of the minor in employment calls for close cooperation with the plant physician. Many physicians in industry have little confidence in the signed statement or certificate of health of an outside physician on the yellow "promise of employment" card as to the minor's physical ability to do the work called for. This card is frequently filled out after a meager inspection of the youth, the physician perhaps feeling that, because signing the card is a gratuity, his duty has been discharged by the signature and inspection alone. But there is an aspect of the case in these fourteen to sixteen-year children which is becoming more and more recognized. They constitute the future prospects of our industrial help and with this in view the physical examination by the industrial physician before they enter industry has, as a dominant motive, the conservation of their health, growth, and vitality. An employment manager relies very strongly for the job placement of these cases on the report of the plant physical examination. Backward cases are at this time much easier recognized and remedied. Not infrequently the employment manager is faced by the problem of economic necessity of hiring a backward youth where the family is large. Here consultation is essential in the selection of suitable work.

A similar function of consultation is implied in the treatment of requests for transfer because of fancied grievances about the job. Here the element of fake or malingering appears. We have the lame arm, the sore shoulder, stiff back or splitting headaches—anything as an excuse to change to another department, although there may be no real basis for the change. Investigation of these cases by the employment manager demands a report of the real physical condition of the asserted injury before he can justly deal with transfer.

The taking into employment of women recently widowed and with dependents is a medical risk, for they have presupposedly passed through a recent severe nervous strain. In these cases the need of quiet and the element of an increased fatigue reaction demand work where the nervous strain and noise are lessened, and the worker needs an occasional checking up of her physical progress through the Medical Department.

Another difficulty which frequently calls for consideration is the finding of a temporary job for those well advanced in convalescence from illness or operation and able to do rather light work but still unable to return to a strenuous job. They badly need the money in the weekly pay envelope. Perhaps this problem of temporary placement is one of the most frequent which arises, partly because the idea has to be sold to the foreman. For the foreman's first impulse is to tell the convalescent to 'stay out till able to do what he or she had been accustomed to previously, and it is a self evident fact that danger lurks in the placing of such a case without medical advice and consultation.

Again, we experience the problem of a psychological condition arising from a monotonous job continued for years. A case in point is that of Mrs. D., a weaver, who became an extremely nervous woman, through a long period of seventeen years' work on one monotonous job. After consideration of her case it was decided to substitute replacement at other work, and she made a rapid and uninterrupted recovery.

Fears or phobias occasionally arise. This happened recently to one of our doffers who refused promotion through a fear of moving machinery. This problem was solved by suggestion of varied work which built up a gradual confidence, overcame her fears, and in the end the girl accepted promotion.

### Substandard Risks

A pre-determination of poor accident risks, mental or physical, is absolutely essential to the proper placing of the worker. Because, in the industry employing the writer, organized service work is not yet two years old, numerous cases crop out among those hired in the old days. These present problems similar to those of the new help. A few examples may prove of interest.

Shortly after the Medical Department was established some two and a half years ago, a middle aged member of the outside labor gang appeared at

the clinic complaining of a lame back caused as he claimed by lifting a four-hundred pound bale. Examination disclosed in addition a large double inguinal hernia or rupture which had persisted for several years without the support of a truss. Because there had been no previous physical examination of this man, he had for months been subjecting himself to the dangers of permanent disability, and nobody in the Employment Department had known him to be a potential accident risk. On discovering his physical condition, he was immediately transferred to a safer job.

A short time ago an applicant was offered employment as elevator man. Physical examination showed him totally blind in the left eye although there was no apparent visible disability. Therefore, because his position in running the elevator would expose his left side to injury from the loading and unloading of heavy boxes, he was considered an accident hazard on that job, and work where he would not be subjected to bodily injury was substituted.

Another grave accident hazard was that of a man fifty-eight years of age who was sent to the employment manager by the foreman for transfer because he had complained of dizziness on the particular job of cleaning about the high speed roving frames. Necessarily he was then referred to the Medical Department for a report of his condition. Examination showed a case of high blood pressure, hardening of the arteries, and that rare condition, heart block with a pulse of twenty-eight to the minute, a history of five fainting spells in the past week and constant danger of apoplexy. It did not take many minutes to transfer this man to relative safety. Not long afterward this man dropped dead at his breakfast table.

Then there was a case of a head doffer who was continually tripping up or getting bumped into. Finally because she became a lost time accident case, and repeated this the day she returned to work, her foreman sent her to the Medical Department. The woman was found to have no sight in her right eye and very limited vision with the left. She did her best to fake a good eye examination but was readily recognized as a bad accident hazard and placed at a table cleaning the yarn off of old bobbins. This happened over a year ago, and although in the previous year she had been treated not less than eight times for injuries, since then she has been totally free from them.

These examples suffice to show the

very close relationship which exists between the proper functions of employment and medical departments. Both departments are irrevocably bound up in service, that great work of bettering industrial relations. The employment manager today not only works to produce a better man for the job, but he is going a step farther, and works to produce a better job for the man. In the process of humanizing industry there is no finer introduction to a workman's confidence than a sincere interest in his general well being and progress as manifested today by the joint solution of his problems by the industrial physician and employment manager.

### Physical Education Meeting at Chicago

That the physical education program has become international in scope was pointed out by John J. Tigert, United States Commissioner of Education, before the Fifth National Physical Education Conference held at the Great Northern Hotel, Chicago, February 28. From a questionnaire sent out by the United States Bureau of Education relative to physical education, 16 of the 37 foreign countries who answered have physical education in the schools. The playground, a typically American institution, is also being established in European countries.

The need for physical education by a city and industrial people was discussed by Will C. Wood, State Superintendent of Schools of California. Physical education must not only conserve vitality but it must increase physical vigor, stated Mr. Wood. It must build up the nervous system as well as give it relaxation; it must train for hygienic living and good sportsmanship; it must provide for the increased problem of leisure.

The Conference was held under the auspices of the Council of State Superintendence of the National Education Association. Dr. W. S. Small of the United States Bureau of Education was chairman.

According to statistics based on amounts disbursed for deaths during 1921 by the Metropolitan Life Insurance Company, tuberculosis ranks as the greatest cause of death, 14.3 per cent of the deaths being from that cause. Mortality from other diseases ranks in percentages as follows: Heart disease, 12.2; cancer, 9.4; chronic nephritis (Bright's Disease), 7.4; pneumonia, 7.0; cerebral hemorrhage apoplexy, 6.5.

# Cooperative Medical Aid for Injured Workmen

## A Plan Combining the Free Choice of Physician and the Contract System

BY HOMER D. DUDLEY, M.D., F.A.C.S., INDUSTRIAL SERVICE BUREAU, SEATTLE, WASH.

IS IT possible to devise a cooperative plan for giving the best medical and surgical service to injured workmen under state supervision which will be mutually satisfactory to physician and to patient? Can the injured workman have the free choice of physician under a contract plan to furnish medical and surgical aid, and can such practice be distributed so justly that the members of a large organization of doctors will be content? These questions are answered affirmatively by the Industrial Service Bureau of the King County Medical Society, an organization comprised of the leading physicians in the most populous county in the state of Washington.

The Industrial Service Bureau is unique in several particulars. With more than four years' experience, it is able to show that physicians in so numerous a group as a large county medical society can bargain collectively and can render a service unsurpassed elsewhere in the state or in the entire country, to injured workmen who are beneficiaries of the industrial insurance plan. The plan under which the Bureau operates is a rare thing in contracts—it is entirely satisfactory to every interested agency. The Industrial Service Bureau of the King County Medical Society probably has no counterpart in the country, and the story of how a county society of doctors makes contracts to render medical and surgical service, discharges its obligations to injured workmen satisfactorily, and apportions the work with even handed justice is worthy of consideration.

Washington was one of the first states to adopt a Workmen's Compensation Act. In 1911 when the law was enacted, it was not foreseen that the compensation provided frequently would not pay for necessary dressings, drugs, hospital care, and for the services of the attending surgeon. After a few years of trial, it was seen that the compensation act failed to provide the relief which injured workmen had the right to expect. The dissatisfaction over the operation of the law was not confined entirely to the workers; the physicians who attended them when accidents occurred

*The Industrial Service Bureau of the King County (Washington) Medical Society probably has no counterpart in the country. The accompanying article is the story of how a county society of doctors makes contracts to render medical and surgical service, discharges its obligations to injured workmen satisfactorily, and apportions the work even handedly.*

*The bureau was organized to coordinate two plans devised for rendering relief to injured workmen under the Medical Aid Act, one plan permitting industrial plants to enter into contract with individual physicians to furnish medical service; the other plan giving the injured employee the free choice of physician.*

found difficulty in many cases in collecting their bills. No attachment proceedings or garnishments against this fund were permissible under the law, and it frequently happened that the injured workman, who had been reduced to straightened circumstances by reason of his unemployment, received his small compensation from the state and left the attending physician to look in vain for his pay.

The original act was defective in another particular. While it relieved the employer from liability of damage suits, the flimsiest pretext was considered sufficient upon which to base a suit for damages for alleged malpractice against the doctor. The physician was practically the only person left who could be sued, and for several years after the enactment of the compensation act, malpractice suits were so numerous that all commercial liability insurance companies withdrew from the state. It was not unusual for physicians to refuse cases which came under the compensation act, owing to the rather general tendency to sue under the least possible provocation.

It should be mentioned, in passing, that the withdrawal of the liability

insurance companies from the state reacted beneficially by making it necessary for the doctors to provide their own insurance. This they did on a cooperative plan. It has been found possible, for a nominal fee of ten dollars a year, to provide a defense fund which has given more satisfactory protection and now has a surplus of nearly \$12,000.00 in its treasury.

The deficiencies in the Workmen's Compensation Act finally impressed the state legislature and remedial legislation was passed in 1917. This supplemental law was known as the Medical Aid Act. It was designed to give relief to employees injured in the industries by furnishing complete surgical service and hospital care in addition to partial remuneration for loss of time. The administration of the act was placed in the hands of a board composed of one representative of labor, one representative of the employers, and a doctor of medicine. This board was empowered to make rules and regulations for carrying out the provisions of the act which had the effect of statute law. Its administration was generally satisfactory to the employees and to the industrial surgeons.

Under the original compensation act, the fund was derived wholly from the industries and taxed on a basis of the number of employees in each plant. The Medical Aid Fund, however, was obtained from employers and employees, each group contributing one half. The assessments were classified as to the hazards of each industry and ranged from one to three cents a day for each employee, according to his classification. Ten per cent of the total amount derived was devoted to administration expenses, while the remaining 90 per cent went to a fund to provide for the care of the injured workmen.

The Medical Aid Board, which has been superseded under the provisions of the new civil code by a supervisor of industrial insurance, devised two plans for rendering relief to injured workmen. One plan permitted industrial plants to enter into contract with individual physicians or associations to furnish medical service to in-

jured employees. The consent of a majority of the workmen was required to make such a contract valid. The other plan gave the injured employee the free choice of physician who was paid according to an established schedule of fees, the state retaining full supervision over the treatment and hospitalization of the beneficiary.

### Combination Plan Problems

In meeting the changed conditions, a committee of physicians in King County made a survey of the industries. It was found that under the original act approximately 95 per cent of the medical contracts were held by about 5 per cent of the membership of the county medical society. So long as it was optional with the employee whether he should pay into hospital benefit funds or remain free to choose his own physician, there was little concern over these contracts. However, since the Medical Aid Act compelled every employee in the hazardous industries to contribute to the medical aid fund, it became apparent that some fairer plan for distributing this practice must be devised. The principle that the humblest patient was entitled to the best possible medical and surgical attention of his own choosing was considered fundamental. The provision of the law which gave the patient the right to choose his own physician was so excellent that it was imperative that it be retained. The problem, then, which confronted the King County Medical Society was to devise a method which embraced both the contract system and the free choice of physician plan. The solution was found in the organization of the Industrial Service Bureau, an adjunct of the medical society but having behind it all the resources of the parent association. This organization was accomplished in June 1917 and the Bureau has functioned ever since.

It was not an easy matter to formulate a plan which would meet all objections. Since the Committee appointed by the Medical Society was doing pioneer work, it had to take each step cautiously and with due regard to the rights and privileges of 428 doctors who were members of the organization. The list of physicians was so large that it was possible to give injured workmen wide range of choice, but it was necessary to prepare a form of contract which would bind the Society and outline a plan under which the industrial practice could be equitably apportioned. As a matter of fact, it required several

months of hard work to find a solution to the problem. When the completed plan was proposed, the ability of the society to discharge its obligations and its guarantees were so ample that the state authorities, many employers, and their employees received it with enthusiasm.

The entire resources of the Medical Society were made available to the workmen injured in the industries. The most skillful industrial surgeons and the highly trained specialists in all branches of medicine and surgery were on call when desired. The best hospitals, the most competent nurses, and the well equipped technical laboratories were available for the treatment of their injuries. It was foreseen that not all the members of the society would seek this class of practice. It was to be expected that doctors who had arrived at that prosperous state when they could refuse calls and meet their patients only by appointment or who excluded emergency surgery in their practice would prefer not to accept accident cases.

### Calls Are Apportioned

Actually only about one-half the membership of the society registered their names as willing to take industrial cases but in practice no member refuses a case where his services have been specially sought. Usually the calls are apportioned among those registered, but it is not unusual to have requests for a physician not on the list. In a case of this sort, the physician serves without question. In a majority of instances, a preference is indicated when a physician is called; when no preference is expressed, selection is made at the central office from a rotating list.

The unquestioned responsibility of the society, an incorporated body, makes it possible to give a smaller bond than that ordinarily required of an individual or group. The rule promulgated by the Medical Aid Division requires a bond of \$10,000.00 for the first contract and an additional bond of \$250.00 for each subsequent undertaking. Had this rule been strictly adhered to in the case of the Industrial Service Bureau, the total amount of the bonds would be in excess of \$85,000.00. In view of the quality of service rendered and the fact that every member of the county society stood behind the contracts, it was deemed sufficient to require a bond of only \$20,000.00. As a matter of practice, the bureau has uniformly given more service than is actually required under the agreement.

Following is a brief summary of the service rendered: (1) A twenty-four hour service through a telephone exchange with five trunk lines employing three operators; (2) a choice of any physician from the bureau's list of doctors classified as to their specialties; (3) in the event that the doctor chosen is not immediately available, an emergency service is furnished and the physician selected by the injured workman subsequently takes charge of the case; if no preference is expressed, the bureau furnishes a doctor from a rotating list of physicians who have agreed to be on call for that day; (4) a fully equipped first aid station with a graduate nurse in charge in each plant or neighboring group of plants employing one thousand or more workmen; (5) consultation is furnished in all serious cases; consultation when requested, and consultation covering the various specialties whenever indicated; (6) first aid cabinets with free lectures weekly to designated first aid men in the various industrial plants; (7) free ambulance and hospital care when needed; (8) private nurses and private hospital rooms in serious cases when advised by the attending physician.

It is worthy of note that the first aid kit supplied by the Industrial Service Bureau was the first voluntarily furnished in the state of Washington. Since its appearance, plants are now required by law to supply emergency outfits. The contracts call only for ward beds in hospitals, but in serious cases, upon request of the attending physician, the bureau furnishes private rooms and special nurses during the critical period of a case.

### Benefits to Physicians

It is beyond question that in the operation of the bureau every employee has the benefits of both the free choice of physician plan and the contract plan, plus the unsolicited services of the consultants and specialists, the daily reports of condition and progress of the patient available both to the bureau and the employer, the supervision of the first aid men, and a prompt and effective ambulance and emergency surgical service.

The benefits of the bureau to the individual physician may be summarized as follows: (1) Every doctor enjoys all the patronage from any industrial plant or individual employee he would have had were there no Medical Aid Act; (2) the doctor is relieved of the tedium and worry

of bookkeeping, the handling of funds, operation expenses, the settlement of accounts, and the time consuming work of settling disputes; (3) surgeons are relieved of the liability of catastrophes which might prove financially disastrous if they held individual contracts; (4) all accounts are settled in full every thirty days according to the schedule of fees established by the state; all are paid in full for every service rendered; (5) every doctor registered in the bureau has an equal share in the patronage which might come to him by chance. The continuous central telephone service and the rotating list make it possible to be solicited for a service which might not otherwise be requested; (6) any plant under contract with the bureau may, if it wishes, specify the same doctor in every accident case if the choice is agreeable to the injured workman. Many physicians turned over their individual contracts to the bureau; (7) a committee of doctors audits all bills on the first of each month and checks are forwarded on or before the tenth.

#### System of Blanks Devised

The Industrial Service Bureau employs five persons; three telephone operators, a detail office man, and a manager. The manager is a layman under contract and bond whose remuneration is based upon a sliding percentage of the profits of the bureau. The doctors in any instance cannot lose. If, after all expenses are paid, a profit remains, a percentage is paid to the manager and the remainder goes into the treasury of the county medical society.

The system of bookkeeping, office blanks, and registration of calls was devised after much experience. It is now so complete that it appears to meet every requirement. Among other things, it is designed to make a permanent record of each call, the name of the plant calling and the hour, the physician designated or the physician furnished, the name of the patient, the nature of the injury, the destination of the patient, the time of arrival at the hospital, the time of the arrival of the physician, and the number of physicians called preceding the acceptance of the case. A simple ledger and card system gives the service rendered by each physician, the names of the patients, and the fees paid. Also there is a separate record for each industrial plant which shows the amount of money paid, the cost of carrying the contract, the number of accidents, and the names of the injured workmen.

From these records, it is possible for every interested party to obtain any desired information.

The state law provides that if any individual plant can show a reduction in the number of accidents through the installation of safety devices or through the exercise of commendable caution, it may have a reduction in the assessments against its particular classification. The records of the bureau are designed to supply the industrial plants with facts and figures to make this showing. The information is furnished gratuitously.

Some of the facts shown by the bureau records are extremely interesting. After nearly five years of experience, it has been found that 50 per cent of the accidents in industrial plants occur on Monday or on the day following a holiday. Twenty-five per cent of the accidents occur shortly before quitting time. From these facts, it is deduced that from 60 to 75 per cent of accidents are due to carelessness; that after a holiday the workman is slow to get back into routine of duty and that the haste to quit work presumably results in throwing aside the usual precautions against accident.

The satisfactory operation of the bureau has assured its permanency. Upon several occasions state officers have expressed the conviction that in view of the class of service given and the smooth running qualities of the bureau, it is almost ideal. Despite the fact that 428 doctors are under contract no more disturbance is caused the state department of labor and industry than if the contracts were held by individuals. It is a demonstration of the fact and the realization of a belief that when proper system is established a group can operate as smoothly with greater benefits and efficiency than an individual. The plan imposes no greater cost on the plants and employees than individual contracts or the free choice of physician system. As a matter of fact, it costs a little less since the bureau furnishes ambulances and first aid equipment. Also it saves the time of the plant in calling doctors and the service is generally more prompt.

Among the indirect benefits of the bureau to the medical profession in Seattle and King County may be counted the physician's exchange which is operated in the same offices and by the same force. With a list of physicians constantly on call, any person in any part of the city or county needing the services of a doctor can be supplied by the bureau.

There is also a collection bureau housed in the same offices under the same management which is able to take a serious burden from the shoulders of the members of the society. It should be mentioned that the medical society contracts to care only for those industrial accident cases which come within the provisions of the Medical Aid Act.

The advocates of State Medicine might find in this plan a substantiation of their theories provided the same cooperation of all interested parties could be obtained. The difficulties in the way of securing this cooperation probably are in the light of present medical practice almost insurmountable. That, however, is a question which may well be left to the future for determination.

#### Seating of Negro Women in Industry

One of the most injurious conditions surrounding thousands of Negro women in industry, the arrangement of seating them when at work, was revealed by the investigation made recently by Miss Emma L. Shields of the Woman's Bureau of the United States Department of Labor. States the report:

It has been physiologically proved that continuous standing, or sitting on improperly adjusted chairs, is particularly injurious to the health of women, and that one of the best methods of relieving their fatigue and strain is to provide adjustable seats for use while at work. The managers of the plants included in this survey, however, seemed generally to have ignored this very important matter, as seen in the fact that 128 establishments, employing 10,115 Negro women (86 per cent of all) were found to have either makeshift seats or none at all. These makeshift seats usually were stools or wooden boxes with no back supports. Occasionally the women had tried to relieve this latter situation themselves by nailing a straight board to a box. Even where better seating was provided there was apparently little adjustment possible between the height of the work table and the chairs. A strained posture consequently was unavoidable.

Continuous standing with no facility for sitting was quite common. Many managers were emphatic in their avowal that certain of the processes on which Negro women worked could not be performed while sitting, yet in other establishments women were comfortably seated while performing these same operations. Ten managers said the women would go to sleep if they provided them with seats, but there was no evidence that this happened in the places where seats were provided. The responses of employers to suggestions about such conditions showed clearly that many were eager to remedy them.

# Massachusetts Lighting Code

**S**UGGESTIONS for lighting industrial establishments are presented in a tentative code published by the Department of Labor and Industries. This code was prepared by a committee appointed by the Department to submit rules and regulations. Its membership includes lighting experts, industrial engineers, ophthalmologists and representatives of employers and of labor, made up as follows:

Dr. Louis Bell, chairman, Federal Committee on Lighting, Boston; Dr. Walter B. Lancaster, ophthalmologist, Harvard Medical School and Massachusetts Charitable Eye and Ear Infirmary, Boston; Dr. Harry Linenthal, Harvard Medical School, Boston; Dr. Frederick H. Verhoeff, ophthalmologist, Harvard Medical School and Massachusetts Charitable Eye and Ear Infirmary, Boston; Dr. Wade Wright, Division of Industrial Hygiene, Harvard Medical School and Director of Industrial Clinic, Massachusetts General Hospital, Boston; S. E. Whiting, Liberty Mutual Insurance Company, Boston; Edward M. Coffin, staff engineer, Associated Industries of Massachusetts, Boston; Charles F. Horan, director of safety, Hood Rubber Company, Watertown; John Newington, expert on lighting for New Bedford Cotton Manufacturers' Association, New Bedford; Harry Jennings, business representative, Boston Central Labor Union, Boston; and Leonard W. E. Kimball, Electrical Workers' Union, Local No. 103, Boston.

The presentation of the code in tentative form is to afford opportunity for employers to try out the recommendations before a mandatory code is adopted; and to enable the Department to secure additional information as to the lighting intensities required for specific industrial processes.

There is no obligation upon any employer to adopt these requirements at the present time. The Department recommends, however, that so far as possible employers test them in their establishments to ascertain to what extent they are now meeting the provisions.

The code presented here differs but little in its main provisions from the code recently approved by the American Engineering Standards Committee. A public hearing for the purpose of adopting a lighting code will be held at the State House on May 16,

1922. After the hearing the department will determine, from the information obtained through the suggestions submitted and through its own investigations, what form of code it is advisable to adopt.

The code as tentatively arranged follows:

## Rules and Requirements

**Rule 1, General Requirement.**—Working or traversed space in buildings or grounds shall be supplied, during the time of use, with artificial light in accordance with the following rules, when natural light is less than twice the mandatory intensities specified in Rule 2.

**Rule 2, Intensity Required.**—The minimum illuminations to be provided and maintained are given in the following table:

	Foot candles at the work Minimum re- quired
(a) Roadways and yard thoroughfares .....	0.02
(b) Storage spaces .....	0.25
(c) Stairways, passageways, aisles, toilets and washrooms, handling of rough materials .....	0.50
(d) Rough manufacturing, such as rough machining, rough assembling, coarse textile operations, rough bench work .....	1.00
(e) Rough manufacturing, involving closer discrimination of detail .....	2.00
(f) Fine manufacturing, such as fine lathe work, pattern and tool making, fine textile operations, office work, such as accounting, typewriting, ... ..	3.00
(g) Special cases of fine work, such as watch making, engraving, drafting; close work on dark colored textiles .....	5.00
(h) Extreme cases of fine work requiring unusual illumination, such as fine sewing on dark textiles, or furs. Needle making .....	7.00

**Rule 3, Shading of Lamps in Working Spaces.**—Suitable shading shall be furnished as follows:

Lamps shall be suitably shaded to minimize glare.

(1) All lamps in working spaces and placed more than 7 feet and less than 20 feet above the floor shall be so shaded that direct light from them shall be cut off down to an angle of at least 15 degrees below the horizontal through the lower end of the filament, except that lamps having an apparent surface brilliancy not anywhere exceeding an intensity equivalent to 15 c.p. per square inch and 10 feet or more above the floor, and lamps neither exceeding this surface brilliancy nor 50 mean spherical candle power and at least 7 feet above the floor need not be so shaded.

(2) Lamps in working spaces less than 7 feet above the floor shall be regarded as for local lighting and shall be so shaded that direct light from them shall be intercepted down to an angle of at least 30 degrees below the horizontal, and where the work illuminated by them is such as to produce brilliant reflections shall in addition be screened by diffusing surfaces, except for lamps below the workers' eyes and so placed as not to shine therein.

**Rule 4, Distribution of Light on Work.**—Lamps shall be installed in regard to height, spacing, reflectors or other accessories as to secure a good distribution of light on the work, avoiding objectionable shadows and sharp contrasts of intensity.

**Rule 5, Entrance and Exit Lighting.**—Employers shall properly light passageways, stairways, and exits, in so far as their premises are concerned, which means buildings, floors or rooms controlled by the employer, including entrances thereto, but excluding hallways, passageways, and stairways giving access to other floors or spaces on the same floor, and used in common by the tenants of the building, which shall be lighted by the party or parties in control of the building, in accordance with the following provisions.

Under the provisions of the statute an employer who violates any reasonable rule, regulation, order or requirement made by the Department of Labor and Industries is subject to a fine of not more than one hundred dollars. (Section 180, Chapter 149 of the General Laws.)

Lights shall be provided in all stairways and exits of factories and in the passageways appurtenant thereto, independent of the regular lighting of the working space. Such lights shall be served from a source not subject to failure because of the failure of the room lighting, and preferably from an independent connection extending back to the main service entrance for the building. In case of unusual danger which may exist on account of type of building, nature of work, crowded conditions, or lack of suitable exit space, the Commissioner of Labor and Industries may require such lighting to be extended within the working space; and independent service to be ensured by connection to a separate source of supply without or within the building.

**Rule 6, Switches and Controls.**—Switches and controls shall be so placed that at least pilot or night lights, which may form part of the entrance and exit lighting, may be lighted, if not kept regularly burning, from main point of entrance for employees. Such controls shall be plainly labelled.

**Rule 7, Maintenance.**—All lighting equipment shall be cleaned and kept in order by the employer, so that the intensities of illumination shall never fall below those specified in Rule 2, unless from causes beyond their control, and that the provisions of Rules 3 and 4 shall be maintained.

**Rule 8, Natural Lighting.**—Shades, preferably of translucent material or diffusive glass, or awnings shall be used to minimize glare wherever the location of the work is such that the worker must face large window areas through which excessively bright light may at times enter the building.

**Rule 9, Classification.**—Assignment of industrial operations to grades (a) to (h) of Rule 2, and requirements under Rules 3 and 4, shall be determined by the inspectors, subject to review by the department.

The following additional comment is necessary on Rules 2, 3, 8 and 9:

**Rule 2.**—The foot-candle,\* the common unit of illumination, is the light-

ing effect produced upon an object by a standard candle at a distance of 1 foot; at 2 feet, the effect would not be one-half foot candle, but one-fourth foot candle, etc. A lamp which would give off 16 candle power uniformly in all directions would produce a uniform illumination of one-foot candle at a distance of four feet in any direction.

To reach at all times the mandatory values of the column headed "Minimum Required" the initial illumination when the equipment is installed should exceed these values by at least 25 per cent.

Certain operations—for example, photographic processes—are carried out in darkness, but spaces so used must be provided with available lighting grade (c) for use in emergencies.

It will generally be found that the various operations required in a given industry, for example, textile manufacturing, shoe making, etc., require very different degrees of illumination according as they are for rough work requiring little discrimination of detail, or fine, demanding the best conditions for normal vision. For instance, the coarser operations in textile working would generally fall under class (d); the finer ones requiring closer vision either on account of fineness of material or color would be found in classes (e) and (f); and

\*Measurements of illumination are to be made on a horizontal plane, at the work, in (a) at the ground level, with a properly standardized portable photometer. When the work is in a vertical plane, measurement of the standard intensities should be in this plane.

extreme cases of manufacture and inspection of dark fabrics might even run into (g). The same sort of variation over a similar range would be found in other industries. On the other hand, there are classes of rough handling of materials, scarcely to be classed as manufacturing in the ordinary sense, which may fall to class (c), while a comparatively few manufacturing operations in which there must be the closest of visual attention under difficult circumstances would be placed in (h).

*Rule 3.*—Shading of lamps may be either by opaque shades or any shades of which the surface brilliancy does not exceed 15 c.p. per square inch. In localized lighting, screening by diffusing surfaces may be done either by a directly interposed diffusing screen or by reflectors having a diffusing surface combined with bulb frosted or enamelled lamps.

Glare, either from lamps or from unduly bright reflecting surfaces, produces eye strain and increases accident hazard, hence should be rigorously avoided.

*Rule 8.*—To minimize eye strain, diffusive or refractive window glass should be used for the purpose of improving daylight conditions.

*Rule 9.*—These rules may be temporarily modified in whole or in part by the State Department of Labor and Industries with respect to existing installations only, on showing of full and adequate reason for such temporary exception, at a hearing where all interested parties are represented.

sult of his being overcome by gases or fumes or other causes while removing the hot ashes and cinders from the furnaces as that the fall was caused by an epileptic fit. . . . The fact that we cannot overlook or ignore is that Madison, by reason of his falling into the pit while engaged in performing the duties of his employment, was so severely injured that he died from the injuries. He did not die from epilepsy or a pre-existing disease but from the burns he received from falling into the pit.—*Rockford Hotel Co. v. Industrial Commission*, 132, N. E. 759.

THE Court of Civil Appeals of Texas, November 10, 1921, defined the term "hospital services" within the meaning of the Workmen's Compensation Act. The appeal was brought to cancel an award for hospital services rendered by the father to his son. The case in full will not be stated, the question being whether the character of the services rendered are hospital services in the contemplation of the Workmen's Compensation Act.

It requires no argument to show that a private residence, technically speaking, is not a hospital. The statute provides for hospital services. The issue is presented as to what is included in hospital services. Appellant insists that "hospital services" embraces only treatment received in a hospital and does not include "hospital care, meals, fuel, light, and other necessities," for which the charge of \$1.00 per day is made. We do not concur in appellant's contention. . . . The statute does not specify the services to be rendered. . . . and the evidence offered does not show what services are ordinarily furnished by hospitals or other institutions. We can, however, imagine the inconvenience and utter lack of what would be expected of a hospital service that did not furnish some care, meals, heat when needed, and artificial light to a totally disabled employe. We think the service should at least be commensurate with the need.—*Southern Surety Co. v. Beard*, 225 S. W. 240.

THE New York Supreme Court, Appellate Division, on November 16, 1921, held that the poisoning of fingers from dipping the hand in a solution in the development of photographic plates in the course of employment which occurred some five hundred times each day during a week was not an "accident" for which compensation could be awarded, an "accident" being an event which takes place without foresight and expectation and which occurs on the instant rather than something which continues, progresses, or develops.

The court states the facts:

The claimant was employed by a photographer in the development of

## Recent Compensation Decisions

THE Supreme Court of Illinois, October 22, 1921, held that, where an employee while engaged in the performance of the duties of his employment fell into an ash pit and was so burned that death resulted, the same was not from epilepsy or pre-existing disease but from burns received from falling into the pit, and that the case was within the Workmen's Compensation Act.

The facts of the case are stated in the opinion of the court:

Joseph Madison was employed by the Rockford Hotel Company on and prior to September 5, 1919. On that day while in the discharge of his duties he fell into an ash pit where hot coals and cinders were thrown when removed by him from the furnace. He was seen by the engineer a few minutes before he was found in the ash pit in the act of raising the cover from the pit for the purpose of dropping into it ashes and cinders from the furnaces. The witness left the room for five or ten minutes and when he returned found Madison lying on his back in the pit on the hot cinders. He was unconscious, and before witness could procure help and remove him he was badly burned. After Madison was removed from the pit he regained con-

sciousness and was taken to a hospital where he remained several days. He was then removed to his home where he died December 15, 1919.

The doctor who held a post mortem described the conditions he found and expressed it as his opinion that death was caused by the burns.

The widow filed claim for compensation, which was allowed. Liability was denied under the Workmen's Compensation Act on the ground that Madison's injury did not arise out of his employment but was caused by Madison being seized with an epileptic fit; that he was subject to such fits of which his employer had no knowledge; that the fit was the direct and only cause of his injury, and the accident did not arise out of the employment. It is generally held by the English Courts and the courts of this country that, where the death of an employe results from a prior existing disease, like heart trouble or other impaired physical condition, while the workman was doing his ordinary work in the ordinary way, and there was no sudden, unusual or violent strain it will not be considered an accidental death arising out of the employment within the meaning of the Workmen's Compensation Act.

It is contended by defendant in error that it is not as probable that Madison's fall into the pit was the re-

photographic plates. It was necessary for her more than five hundred times each day to dip plates held in her left hand into a poisonous chemical solution. Having performed this work continuously for more than a week, her fingers became red and swollen. She went to a physician who gave her treatment. Eventually the end of the little finger of her left hand became mummified, gangrene set in, and an amputation thereof becoming necessary was performed. The pathological cause of her injuries was the contraction of the blood vessels of her finger through the

gradual action of the chemical solution. . . . It seems to me, therefore, that as the injuries in the case arose from the application of a poisonous solution during the working hours of the claimant for a period of more than seven days, and as the application was voluntarily made, she received no accidental injury for which an award can be properly granted.—*Jeffreys v. Charles H. Sager Co.*, 191 N. Y. S. 354.

Two judges dissented. (This decision is not final there being open an appeal to the Court of Appeals.)

A young physician just completing two years hospital training, and closely associated with a well known surgeon of Atlanta, Georgia, is desirous of securing a position in which he will have an opportunity to do industrial surgery.

The secretary of the American Association of Industrial Physicians and Surgeons occasionally receives inquiries regarding positions for physicians desiring to enter the industrial field.

Just recently the mail brought three such letters and it immediately occurred to the secretary that it would be well if the Association made an attempt to keep informed regarding such matters. By acting as a clearing house for such information, the Association might give valuable advice both to the industries and to industrial surgeons. If you know of any vacancies or, if you know of any physicians desiring a change or wishing to take up this particular type of medical work, will you not communicate with the secretary? It will doubtless be of benefit all around if we can know of such cases.

During the past year the secretary has known of at least a half-dozen opportunities, but in no instance was he able to offer a good suggestion. There is no reason why the Association should not conduct an embryo employment department. Some members of the Association doubtless know of positions which are unfilled, and others perhaps know of excellent physicians who would be fitted for these positions. Can we not get together on the matter and render some real service?

As a result of intervention by the International Labor Office, the Persian government has taken steps to remedy the conditions under which women and children have been working in carpet weaving in Kerman. The new rulings temporarily in force prohibit the employment of children under ten years of age, limits the working day to eight hours, and provides seats for workers, and a mid-day rest period.

A physician connected with the U. S. P. H. S. desires to secure a position with some industry in the West or Middle West. He is a graduate of a Class A school and well prepared to take up industrial work. If anyone knows of a connection he might make, the secretary will be very glad to furnish his name and address.

Up to 1914, comparatively little coal-tar benzene (benzol, CH) was used in the United States. Since then its use has steadily become more extended until now benzene poisoning is a menace in American industry. Alice Hamilton, Boston, reviews the literature in the *Journal A. M. A.*

## ASSOCIATION LETTER

By WILLIAM ALFRED SAWYER, SECRETARY

THE annual meeting of the American Association of Industrial Physicians and Surgeons will be held in St. Louis, Mo., on May 22 and 23 at the Medical School of Washington University. A splendid program is being prepared and the largest attendance in the history of the organization is expected. Many matters of interest and importance will come up for consideration.

Railroads are offering reduced rates for the A. M. A. meeting which is the same week, and it is hoped that as many of our members as possible will avail themselves of the opportunity. The necessary credentials for reduced rates may be secured from the secretary of the American Medical Association. Dr. Louis H. Behrens, 3525 Pine Street, St. Louis, Mo., heads the local Committee on Hotels for the American Medical Association.

The membership drive continues to go forward slowly. A number of our members are doing splendid work in securing new members. Have you done your share?

Following is a list of recent new members:

Dr. Tullie Van Boyd, Morris Packing Company, East St. Louis, Ill.; Dr. W. L. Adams, Fresno Flume and Lumber Company, Fresno, Calif.; Dr. Frederick W. Dersheimer, National Lamp Works, Cleveland, O.; Dr. Frederick Bauer, Plankinton Packing Company, Milwaukee, Wis.; Dr. Thos. H. Wagner, American Steel and Wire Company, Joilet, Ill.; Dr. C. C. Booth, Republic Iron and Steel Co., Youngstown, O.; Dr. C. E. D. Lord, Ruth, Nev.; Dr. H. M. Neale, Upper Lehigh, Luzerne County, Pa.; Dr. M. M. Crawford, Federal Reserve Bank,

New York City; Dr. R. M. Cleary, National Lamp Works, Buffalo, N. Y.; Dr. W. E. Fairfield, Clinic Building, Green Bay, Wis.; Dr. J. E. Morris, Olean, N. Y.; Dr. R. B. Morris, Olean, N. Y.; Dr. A. G. Hubbard, Buffalo, N. Y.; Dr. Lloyd Noland, Tennessee Coal, Iron, and Railroad Co., Birmingham, Ala.; Dr. B. F. Lowry, General Chemical Company, Cleveland, O.; Dr. Belle Thomas, Federal Reserve Bank, New York City; Dr. E. W. Bullock, New England Telephone and Telegraph Co., Manchester, N. H.; Dr. S. W. Hobson, Newport News Shipbuilding and Dry Dock Co., Newport News, Va.; Dr. O. M. Spencer, U. S. P. H. S., Washington, D. C.; Dr. G. D. Ayer, Atlanta, Ga.; Dr. Russell F. Sheldon, New England Confectionery Company, Boston, Mass.; Dr. C. T. Sharpe, Life Extension Institute, New York City; Dr. T. G. Allen, Buffalo, N. Y.; Dr. Emmott Howd, Troy, N. Y.; Dr. J. A. Turner, U. S. P. H. S., Washington, D. C.; Dr. J. W. S. Brady, Harvard School of Industrial Hygiene, Boston, Mass.; Dr. C. W. Kilker, Cincinnati, O.; Dr. G. W. Staben, Springfield, Ill.; Dr. C. E. Dumke, Louviers, Colo.; Dr. R. J. C. Strong, Fairbanks, Morse, and Company, Beloit, Wis.; Dr. G. R. Thompson, Washington, D. C.; and Dr. John S. Alley, Midvale Steel Company, Midvale, Utah.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Shriners Hospitals for Crippled Children

Humanitarian Movement Will Reclaim  
the Child for Himself and Society

By FORREST ADAIR, SECRETARY BOARD OF TRUSTEES, SHRINERS HOSPITALS FOR CRIPPLED CHILDREN, ATLANTA, GA.

INSPIRED by the work of the Scottish Rite Hospital for Crippled Children at Atlanta, Ga., the Ancient Arabic Order of the Mystic Shrine at their last convention voted to establish a central hospital of 150 beds for crippled children at St. Louis in conjunction with Washington University. A survey revealing approximately 480,000 crippled children in the country, however, caused the Shriners to change their plans and to see the feasibility of diverting some of the \$2,000,000 raised for the Central hospital to the construction of five hospitals located in cities in various parts of the country.

Contracts have already been let for five hospitals. For the St. Louis hospital of eighty beds \$150,000 was allowed for grounds; \$300,000 for buildings, and \$50,000 for equipment. For the San Francisco hospital of fifty beds not more than \$250,000 was allowed when fully equipped. For the Shreveport, La., hospital \$250,000 was allowed. For the Montreal, Canada, fifty bed unit \$250,000 was allowed, the same amount being set aside for the Minneapolis-St. Paul hospital. Upon the completion of these hospitals, five others will be built in Portland, Ore., New England, Virginia, Pennsylvania, and in one of the Rocky Mountain states.

During the past decade the minds of the people have been more than ever turned toward the helping of the less fortunate and large endowments have been made, immense sums contributed toward charitable and philanthropic institutions and great foundations created.

Hospitals, sanitariums, and homes

have been founded for the tuberculous, the blind, the deaf, but for some reason one class of unfortunates were in a measure greatly overlooked,—the crippled children. Indeed, there have been homes for crippled children; places where cripples were carried, fed, clothed, and given some little education, but no serious or successful effort was made to correct their deformities and send them back to the homes of their parents where they belonged. Possibly this was because there was a prevalent idea that a child afflicted with clubfeet, infantile paralysis, tuberculous spine, or joints, or any of the diseases that come within the scope of orthopaedic surgery was hopelessly incurable, and even the parents accepted such an affliction as a curse and resigned themselves to bear the cross until a kind Providence removed the child.

### May Become Economic Asset

Orthopedic surgery in the past few years has dispelled the passive attitude of parents and public and has

made them realize that the crippled child need not remain a drag on himself, his family, and society. He may, if properly operated on and treated, become normal with the normal child's chance for physical and mental development. He may be enabled to earn his own living, may become a contributor to the social and economic life rather than a parasite.

Crippled children usually owe their condition to congenital or acquired deformities, to paralysis, or to tuberculosis of the joint and bone. Early treatment is imperative in all cases. Especially following infantile paralysis or tuberculosis of the joint and bone can early treatment save the child months of suffering as well as permanent deformity. Before special hospitals for children were established the treatment was often delayed until the bones had hardened in an unnatural posture and loss of function had become absolute. Often the oncoming of such a disease as tuberculosis of the hip is insidious; the child limps or cries a little; there seems to be no urgency. The condi-

Scottish Rite Hospital for Crippled Children, Atlanta, Ga., which furnished the inspiration as well as the model for the Shriners' nation-wide plan for such hospitals.

Proposed hospital at Shreveport, La., one of the five now under construction by the Mystic Shriners for indigent crippled children.

tion progresses and the child becomes hopelessly crippled. Prompt immobilization of the affected joint, a bed in an open-air ward, and good feeding will not only prevent suffering but will insure in a few months recovery without disability.

The necessity for immediate expert treatment in infantile paralysis is seen when one realizes that this disease is responsible for one-third of the crippled children in the United States.

General hospitals cannot adequately care for the slow and tedious cases of such deformity. The open air wards, the splint and appliance workshops, the educational facilities are not available. In such cases there is no natural convalescence. Operations, manipulations, and even prolonged hospitalization do not finish the treatment. The most thorough after care must prevent deformities from reappearing, weakened muscles from sagging, posture from relapsing. A system of muscle re-education, of teaching the child to use muscles atrophied from long disuse, is necessarily the function of the orthopaedic hospital.

Emphasis is being placed today on preventive measures. Efforts are being made to stamp out poliomyelitis and tuberculosis as well as diseases which often cause congenital deformity. Pasteurization of milk has done much to break the chain of infection in infantile paralysis and bovine tuberculosis. But these diseases are still prevalent and the burden of caring for their victims and restoring them to normal function rests on an enlightened society.

Nearly seven years ago the Scottish Rite Masons of Atlanta, Ga., started in a modest way in two little cottages with twenty beds the Scottish Rite Hospital for Crippled Children. Dr.

Michael Hoke of Atlanta, orthopaedic surgeon, agreed to give his services free. The good results obtained were pronounced by those connected with the hospital as nothing short of miraculous and the little hospital began to attract attention.

#### Growth of Plan Sketched

In order to provide more room, money was quickly raised and a new hospital erected provided with an administration building on the second floor of which were operating rooms and all necessary apparatus and appliances. On either side was a wing one story in height and with ramps leading out to the ground so that the children could be rolled out into the sunshine in wheel chairs and beds. Miss Lillian Carter was made superintendent of nurses of the hospital.

John H. Atwood of Kansas City

visited the hospital and wrote of it as the "Miracle House." Frank C. Higgins, the Masonic writer, had a daughter stricken with infantile paralysis in New York City in the epidemic of 1916 who had spent four and a half years in the crippled children's "homes" in the East. She was admitted to the Scottish Rite Hospital and after five months was made to walk, and Higgins wrote of the hospital in the *New Age*, calling it the "Temple of Babies' Smiles."

During this time Noble W. Freeland Kendrick, Past Potentate of Lu Lu Temple, Philadelphia, became the head of the Nobles of the Mystic Shrine, and as he had had some personal experience with crippled children's homes, his mind and his heart naturally turned toward the crippled child. As this order had about 500,000 members, Kendrick introduced a resolution to assess each member two dollars per annum which would yield a fund of one million dollars a year. His resolution called for the erection of a large central hospital which was to have been built at St. Louis, Mo.

The Shriners elected a Board of Trustees who were entrusted with the carrying out of the spirit of the resolution, this Board being composed of Nobles Sam P. Cochran, Dallas, Tex., chairman; W. Freeland Kendrick, Philadelphia, vice-chairman; Forrest Adair, Atlanta, secretary; Philip D. Gordon, Montreal, Canada; Bishop Frederick W. Keator, Tacoma, Wash.; Dr. Oscar M. Lanstrum, Helena, Mont.; and John D. McGilvray, San Francisco, Cal.

Last September the entire Board met in Atlanta and while here visited

Indicative of the cases that the hospitals will treat is that of Agnes Shumake who was cured of clubfeet in five months at the Atlanta hospital.

Children deformed from infantile paralysis have been straightened after several months of treatment at the Scottish Rite Hospital.

the Scottish Rite Hospital for Crippled Children. They were greatly impressed by the work being done in restoring crippled children to their normal condition and immediately decided that rather than put \$2,000,000 in a large central hospital, which would be inaccessible except within a radius of about 300 miles, they would divide this fund and build several hospitals. As the hospital in Atlanta can be duplicated for about \$200,000, ten such hospitals could be erected with the sum of two million dollars.

An Advisory Board of Orthopaedic surgeons was elected composed of the following: Dr. Robert H. Osgood, Boston, Mass., Chairman; Dr. Michael Hoke, Atlanta, Secretary; Dr. A. Mackenzie Forbes, Montreal, Canada; Dr. Nathaniel Allison, St. Louis, Mo., and Dr. John C. Wilson, Los Angeles, Cal. They will attend all meetings, advise and assist the Board in this work and in the actual operation of the hospitals.

The work that these hospitals will do can be gauged to some extent by the accomplishments of the Scottish Rite Hospital at Atlanta. Here every form of disease coming under the general term of orthopaedics is treated. The present capacity of the hospital is fifty-six beds.

During the first year of the hospital's existence sixty-two patients were received into the hospital and 176 into the clinic. Of these, twenty-seven were cured in the hospital and fifty-two in the clinic, the others being still under treatment at the end of the year. During the second year 157 children were received into the

hospital and 231 into the clinic. Of these, sixty-one were discharged as cured from the hospital and 127 from the clinic. The number of operations performed by the medical staff was 225. In the third year, 100 patients were entered in the hospital and 137 in the clinic. Of these, fifty-seven were discharged from the hospital cured and twenty-eight from the clinic. During the year 190 operations were performed. The fourth year saw the admission of 132 children into the hospital and fifty-six into the clinic. Of these eighty-four were discharged from the hospital and 104 from the clinic. Operations for this year totaled 255.

Typical of the many cases cured at the Scottish Rite Hospital and of the cases that the other orthopaedic hospitals will treat is that of Agnes Shumake of Atlanta, Ga., whose club feet were made normal in five months. Children deformed from infantile paralysis have been straightened and cured after several months of treatment at the Scottish Rite Hospital.

The change in physical condition of these children is also marked by great mental changes. Children who had become glum and despondent, had come to think themselves apart from the normal world, who were on the road to developing psychoses, when treated and cured develop the customary childlike attributes of optimism and hope. Soon they become as carefree and happy as the normal well child.

It is evident that with five or ten such hospitals and eventually one in every state of the Union the Shriners' Hospitals for Crippled Children

will reclaim from dependence and disease many hopelessly crippled.

Children will be admitted to the hospital regardless of creed or fraternal affiliations. They will be treated and cared for absolutely free. The principal requirements are that they be capable of improvement, that they be of normal mentality, and that they be unable to pay for medical service and treatment given.

The Shriners' Hospitals have been established to benefit helpless humanity, to prevent possible pauperism, to turn wealth consumers into wealth producers, and to exemplify Masonic principles.

### The Principles of Ante-Natal and Post-Natal Physiology

One seldom finds a book that contains as much information as the recent volume under the above title by W. M. Feldman, M.B., B.S. (London). The wealth of knowledge embodied in this book of 694 pages presents the reader not only with a great deal of data on the subject of ante-natal and post-natal physiology, but he discusses at length many allied subjects, such as theories of heredity, mechanics of development, and physiology of fertilization, the whole theses displaying a great deal of erudition.

If there is any criticism on this excellent volume it is in the direction of the mathematical insertions scattered throughout the book. In some places the author devoted the greater part of a chapter to the presentation of mathematical formulas that detract from the interest of the book. He erred in the same direction in a previous publication, "The Jewish Child," a most valuable contribution in every other respect.

As a whole, however, one may find in the "Principles of Ante-Natal and Post-Natal Physiology" a great deal of interesting information. The volume would make a valuable addition to the library of every physician and scientist.

LONGMANS, Green & Co.

### Child Workers Injured Receive Benefits

Child workers between the ages of fourteen and sixteen who are injured on their way to continuation school are entitled to the benefits of the workmen's compensation act, according to a decision handed down recently by the Compensation Referee at Philadelphia.

# Open Air Schools in Massachusetts\*

By HARRIET L. WEDGWOOD, ASSISTANT IN SCHOOL HYGIENE, U. S. BUREAU OF EDUCATION, WASHINGTON, D. C.

**A**N INVESTIGATION was made by the Massachusetts Department of Public Health, during the school year of 1919-20, to learn how many open-air and open-window schools were being maintained in the state; how many of these were for physically subnormal children; what modifications and improvements in

(4) What remedial measures (such as abundance of fresh air, lower temperature, frequent or extended rest periods, special attention to nutrition with provision for feeding, frequent and thorough medical examinations with corrective measures, weighing at frequent and regular intervals, systematic keeping of health records, and

(5) An evaluation of the results obtained in open air schools, with some information relative to costs, as compared with other methods of restoring to health the anemic, malnourished, pretuberculous, cardiac, neurasthenic, and choreic child, and of "keeping well children well."

The investigation showed a lack of standard practice, and a variation in standards and in recorded results which rendered impossible an evaluation of results of open-air schools, but the status and trend of the open air movement in the Commonwealth could be more or less accurately determined.

Opinions from school and from health authorities ranged from heartiest approval to just as hearty disapproval, with all possible variations between. Opinions differed as to the need for remedial treatment, and as to the treatment that is efficacious. Some approved of outdoor classes, but not of drafty rooms and fixed seats. Some thought communicable disease the one thing to be dealt with; some thought that nutrition work alone would solve the problem (though whether this meant extra feeding alone or feeding and rest and health habits is not certain). Some thought fresh air the essential feature of the school régime and others the lower temperature. Some gave the opinion that the rest hour was a non-essential; others that it was necessary but should be taken at home, and teachers should not be asked to stay and

The interior of a fresh air school in the Westfield, Mass., State Sanatorium.

the regular public schools could be directly traced to the influence of open-air schools; and what recommendations might profitably be made.

Visitation, interviews and a questionnaire were used to elicit information along certain definite lines:

(1) The number of open air schools and open window rooms in the state; the number of pupils in each; how many physically subnormal children were in these schools and what percentage that number was of the entire school population and what percentage of the entire number of physically subnormal children in the state.

(2) The sentiment of school authorities and of health authorities as to the needs of the physically subnormal child, and the efficacy of the open-air school to meet those needs.

(3) The remedial measures that constitute the essential régime for improving the condition of pupils in these classes; and to what extent these essential features were uniformly provided.

efforts to secure home cooperation in health matters) had been undertaken for other subnormal children, with presumably less marked symptoms, not in special classes; and what features of the open-air school régime had been introduced into the regular public schools with a view to "keeping well children well."

Setting up the camp cots on the roof at 10 degrees Fahrenheit at Chelsea, Mass.

\*Summarizing a survey and comprehensive report on this subject made by Miss Wedgwood in her former capacity as Health Instructor, Division of Hygiene, Department of Public Health, Massachusetts.

see that pupils rest; others, that lack of rest was partly responsible for these children's lowered vitality, that conditions at home did not permit the child to rest during the day (hardly at night), and therefore the rest hour must be provided at school and the child be *required* to rest.

Opinions and practice in regard to extra feedings for children differed. A few thought the feeding of school children, under *any* circumstances, an unnecessary and dangerous practice. Some believed that the lunch should be paid for by the child, and that most children could be persuaded to pay the small sum asked for the mid-morning cup of cocoa or of milk. The visitor observed, however, in some of these schools that a few children in the open air classes did not pay for lunch, and such children went without the lunch. Some teachers expressed the opinion that the better habits of eating learned at school, where pupils sat down to meals together, contributed very much to their general improvement. They learned to like vegetables and other healthful foods, ate more slowly and in a happier frame of mind than at home.

Medical examination of these children varied tremendously in different places as to frequency and scope. Weighing and measuring varied from weekly to annually, or semi-annually. The average monthly weight gain varied from 5.21 ounces to 13.43 ounces, the latter average being in a school with windows entirely open, with mid-morning lunch and noon meal provided, and a sleep period on cots in the open air.

The temperature varied from no artificial heat whatever, to a regulated temperature of 60 degrees. The type of schoolroom varied from the open pavilion (in a hospital school) to rooms with windows on one side that could be opened for half the window space, and a cheese cloth covering over this space to keep out dust. Some of the rooms were on the ground floor, some on the second or third with toilets in the basement. In the case of children with heart weaknesses, the number of flights of stairs to climb is important.

In the year of the investigation, ten cities had open window rooms: Andover, Boston, Cambridge, Chelsea, Lowell, Lynn, New Bedford, Newton, Springfield, and Worcester. Attleboro and Braintree were planning to open classes in September, 1920. The inquiry showed about a thousand *well* children in open window rooms of public schools with mid-morning

lunch provided. There were 1,137 subnormal children in the open air public schools and 690 in sanatoriums and hospital schools, a total of 1,827 subnormal children in open air schools, or three-tenths of one per cent of the average membership in the public schools of Massachusetts.

The report on the investigation suggested that an experimental study

be undertaken in order to arrive at some definite conclusions with reference to open air schools; and a number of schools expressed their willingness to cooperate in such an experiment, if it should be made.

Similar experiments carried on in New York City schools have resulted in higher scholarship and improved conditions of health.

Here the curative effects of sunlight are combined with the virtues of open air at the Heliotherapy Open-Air School at Westfield, Mass.

## California Social Work

**T**HE California Legislature has before it a bill defining social work and social worker as well as providing for the examination and registration of social workers. A person misrepresenting himself as a registered social worker is penalized under this bill, the fine being not less than \$10 nor more than \$100 for the first offense.

The bill defines social work and social workers as follows:

The term "social work" as herein used is declared to mean all protective and preventive work such as applies to traveler's aid, dancehall supervision, social hygiene, and other protective and preventive work; all relief work such as applies to relief organizations or to medical social service; all child-caring work, including character-building work, in children's institutions; all correctional work, including that generally performed by probation officers, parole officers, prison workers, workers in correctional schools and detention homes, and workers with the subnormal or mentally handicapped; all welfare work, including that generally

employed by non-commercial employment agents, personnel managers, and welfare workers; all settlement work, including that pertaining to community organization, settlement club work, physical training in settlement work playground work and the like; field investigation, in its bearing upon housing and immigration, or upon supervisory agencies for welfare work, or upon endorsement agencies; the work of social service executives; all welfare work in educational institutions; all form of social welfare work. The term "social worker" as herein used is declared to mean a person engaged in social work, as that term is herein defined.

The bill was drafted by social workers and endorsed at the recent meeting of the California Conference of Social Work. The *Survey*, in noting its possible effects, says:

"R. N." has become the accepted trademark of the registered nurse. Representing as it does, a standard of training and a certain proficiency, it is as zealously guarded as the "M. D." is by the medical profession. If this bill passes, perhaps "R. S. W." will become the nomenclature of the registered social worker in California.

# Food Knowledge the Basis of Nutritional Control\*

## Physical Growth, Mental Vigor, the Ability to Get Things Done, Depend Upon the Diet

BY ALICE M. HEINZ, M.A., FORMERLY DIETITIAN FOR THE CALIFORNIA STATE BOARD OF CHARITIES AND CORRECTIONS, LOS ANGELES, CAL.

THAT the upper limit of the size of an animal is determined by heredity and the stature to which an animal may actually attain within this definitely fixed limit, is directly related to the way it is nourished during its growing period, concluded Waters, one of our nutrition workers, after a series of experiments along this line. Since this conclusion is based upon scientific study, it proves the urgent necessity of the intelligent feeding of children, for, after all, growth studies pertaining to other growing young animals will apply to children as well.

If we would be sure that a proper diet is being selected, the following points should be given due consideration.

Any properly balanced diet for growing children must contain:

(1) Foods which will yield sufficient heat and energy for the needs of the body, in other words, must have sufficient caloric value.

(2) It must supply the proper food elements for replacing worn out tissues whether these be bone, muscle, or nerve tissue, but, over and above this, it must be ample enough and so selected as to supply

(3) The food elements necessary for the growth and formation of new and enlarged tissues—bone, muscle, brain, nerve, and tooth, a dietary requirement which we need not consider in the case of an adult.

### How Must One Eat?

In order, then, that children may grow up to be strong and sturdy of

body, straight limbed, and blessed with good sound teeth, it is essential that those whose responsibility it is to select the diet, acquire some knowledge of food values.

Formerly much emphasis was laid upon the caloric value of a diet. All foods, whether they be protein, fats, or carbohydrates, yield a given amount of heat in the process of com-

Underwood & Underwood.

There are critical periods in the child's physical career when deficient nutrition means arrested processes that cannot later be made up. Rowntree in his "Poverty" differentiates between earning insufficient to attain the minimum necessities and the "secondary" poverty where deficiencies result from unintelligent household budgets. Nutritional work, therefore, becomes a branch of applied economics.

\*This is the first of a series of practical articles on foods and nutrition based upon specific studies made by Miss Heinz for the State Board of Charities and Corrections, California.

Underwood & Underwood.

Los Angeles physicians have established a "Mothers' Educational Center" where parents can bring their babies for mental and physical tests, and may gain reliable recommendations on child care and obtain in the scientific supervision of their children a practical demonstration of the relationship between diet and ordered development.

bustion. The unit by which we measure such heat is termed the calorie, which is the amount of heat required to raise four pounds of water one degree Fahrenheit.

Each of our food principles yield a different number of heat units: one gram of pure protein will furnish four calories; one gram of fat will furnish nine calories; one gram of carbohydrates will furnish four calories. These are the approximate physiological fuel values of the food constituents, allowance having been made for loss in digestion.

Various factors govern the heat requirements of the individual, chief among which are age, activity, sex, and climate. Children require a greater number of calories in proportion to their size and body weight

than do adults, this because of their greater activity and growth, and because they radiate heat more rapidly.

The following table will show the approximate number of calories required by children of different ages. These are only average figures and individual children will require more, or possibly less, according to their rate of growth, activity, and size.

Age	Cal. Daily
1- 2 years inclusive	1,000-1,200
2- 5 years inclusive	1,200-1,500
6- 9 years inclusive	1,400-2,000
10-13 years inclusive (girls)	1,800-2,400
10-13 years inclusive (boys)	2,300-3,000
14-17 years inclusive (girls)	2,200-2,600
14-17 years inclusive (boys)	2,800-4,000

Foods are classified according to their chemical composition as protein, carbohydrates, and fats. Some are

fish, and cheese, while cereals, legumes, and nuts furnish the bulk of our vegetable proteins.

Animal proteins are capable of building body tissue with far greater efficiency and ease than are vegetable proteins. This is due partly to their chemical structure and partly to a difference in absorption.

The best protein food to select for a child's diet is, of course, milk. The curd of the milk is the protein or casein, combined with some of the mineral matter, chiefly calcium. If a child's diet contains a sufficiency of eggs and milk, we need not be concerned about the omission of meat from the diet, especially in the case of the nursery children. Since the nutritional value of eggs, meat,

the essential vitamins, Fat Soluble A. Vegetable fats like peanut, corn, coconut, and cotton seed oil, some of which are used in the manufacture of butter substitutes, do not yield any vitamins, and their substitution to the exclusion of butter in any diet unless definitely compensated for in other foods, particularly one allowing only a minimum amount of milk, also, should be rejected as very poor, really harmful economy.

### Carbohydrates Supplement Diet

The average diet furnishes an ample, if not excess amount of starches and sugars, foods usually classified, together with cellulose which forms the fibrous structure of plants, as carbohydrates. Starches and sugars supply heat and energy to the body but when taken in excess, they build fatty tissue; however, they have never been known to build muscle tissue, or bone, or nerve tissue. This is an important thing to be borne in mind, for it means that sweet foods as well as starchy foods, will not build strong muscular bodies, even though they may aid in producing a sleek looking one. Carbohydrates have an important place in the diet, but they are not to be regarded as substitutes for proteins and fats, but should be looked upon as supplements.

It is highly advisable not to develop in children a desire for sweets. McCollum of Johns Hopkins says it is as great a crime to develop in a child an abnormal craving for sweets as it is to develop in him a taste for alcohol. Candy and sweets should be regarded as food. Their place in a

Nutrition class formation in School No. 9, Rochester, N. Y. The children are seated in the order of their respective gains. Parents are seated back of them. The physician is conducting the class, the nutrition worker is seated. The school principal and director of health education are standing. This group not only sees that gains are made, but teaches the whys and wherefores of the procedure.

rich in mineral matter, therefore valuable in the diet, while others furnish the necessary vitamins. Today the two latter are considered of primary importance in the selection of a proper diet, and the old time calory has been relegated to a place of secondary consideration.

### The Protein Foods

The protein foods are those which contain nitrogen, hence also spoken of as nitrogenous foods. They are the particular foods which will build muscle tissue, indeed, they are the only foods which will do this and they are, therefore, of great importance. We have two classifications of proteins, namely, the animal and vegetable proteins. The animal proteins are those found in eggs, milk, meat,

cheese, and fish as well as milk, is not very different, these may be used interchangeably in the diet, as for instance, macaroni and cheese made after a good recipe, or an omelette, being equivalent to a meat dish.

Animal proteins, that is, the foods containing these proteins, also supply heat to the body and furnish mineral matter and the essential vitamins, the latter being found chiefly in milk and eggs and to a smaller extent, in the other foods.

### Fats for Hardiness

Fats in a diet yield heat in the process of combustion and are essential for the development and nourishment of brain and nerve tissues, besides which animal fats like butter, beef suet and cod liver oil furnish one of

Tuberculosis Association. The nickel-in-the-slot luncheon has its advantages in affording a choice of viands to meet individual tastes. It is a distinct menace unless the person served knows and applies in his daily ration the fundamentals of nutritional requirements. The man poorly fed lacks force.

Rochester, N. Y., nutrition class graduate whose gain was 9 $\frac{1}{4}$  pounds in thirteen weeks, or 498 per cent of the normal rate of gain. There was no guess work or haphazard method in this case, as his chart will show. Photograph through courtesy of Dr. Murlin, of the University of Rochester.

diet is with a meal, and not before or after a meal. Sugar is irritating and usually constipating. It is readily fermented in the stomach causing a form of indigestion; moreover, it combines with any calcium present in the diet, thus robbing the body of some-essential mineral matter. Lastly, sweets take the edge off an appetite and cause children to refuse more nutritious and essential foods, which is the most serious argument against the promiscuous feeding of sweets.

Cellulose, another of the carbohydrates, is digested only when in a young and tender form but even in its older and indigestible form it is of great value because of the necessary bulk which it supplies to a diet.

### Mineral Matter Essential

Besides the food constituents already mentioned, two others even though required in smaller amounts by the body, are of equal importance in any diet. These are, first of all, the mineral matter, and secondly, though of no less importance, the three known vitamins.

Mineral matter is found in every tissue of the body, in all the juices, the blood, bones, and teeth. Calcium, phosphorus, iron, potassium, and sodium are the most important ones, but magnesium, iodine, flourin, etc., are also necessary to the body. Milk is our chief source of calcium. Green vegetables furnish iron, spinach being especially rich in iron. Raisins also

contain a large percent of iron. Phosphorus occurs in combination with fats, as in the fat of egg yolk and meat, and is found in milk and in many of the vegetables.

Iron is an essential element of hemoglobin and of the chromatin substances while calcium constitutes a larger percentage of the body weight (about 2 per cent) than does any other inorganic element. More than 99 per cent of the total amount of the calcium is found in the bones. Phosphorus is a necessary constituent of brain and nerve tissue.

### The Vitamine Content

Lastly, although their presence in the diet is of very greatest importance, we shall consider the vitamins, the growth promoting health insuring constituents found in certain foods.

At the present time we know of the existence of three specific vitamins, although there may possibly be a fourth. The three vitamins are known as:

(1) Fat-soluble A found chiefly in milk, butter, eggs, beef suet, and in green vegetables. (2) Water-soluble B found chiefly in yeast, eggs, green vegetables, seeds, and cereals. It is also found in some of the root vegetables, although some like the best are wholly deficient. (3) Water-soluble C found chiefly in citrus fruits and in the leafy vegetables. Tomatoes are also rich in this vitamin.

Fat-soluble A is necessary for growth and in its absence there often develops an eye disease known as xerophthalmia.

Water-soluble B is necessary for growth and also for the prevention of polyneuritis or beriberi.

Water-soluble C, the latest to be recognized, is the antiscorbutic vitamin.

Since the discovery of the vitamins, the importance of the leafy vegetables in the diet has become prominent. Because they are especially rich in vitamin content and can be eaten raw in many instances, thereby preserving the full value of the vitamins, these vegetables have been termed the "protecting foods." It is highly essential that these should be included in the daily diet and that all children should be taught and made to eat them.

Let us then, when we plan a diet for children, see that it contains enough milk, about three to four glasses a day for each child, that it furnishes meat or a proper meat substitute each day, and that along with

these things, it supplies butter, some green vegetable and fresh fruit each day. If care is taken to provide these foods, the rest of the diet will take care of itself.

### Food Requirements of Old Age Important

Diet is quite as important for keeping the aged in physical trim as it is for the growing child or the person in mature life, says James Buchanan Stoner, Surgeon, United States Public Health Service in *The Forecast*.

The problem of eating in old age is mainly that of avoiding too much food. The man above sixty should eat just enough food for his needs, he should avoid any foods which lead to indigestion, he should eat slowly, masticate thoroughly, eating only the simplest foods. Meat should be sparingly eaten. Fresh vegetables and ripe fruits, especially cooked fruits, should have an important place in his diet.

Fatness or thinness in old age is largely dependent on diet, and the old person who realizes this will not add superfluous layers of flesh, by overeating. By eating just enough for nourishment the man or woman past sixty can stave off the process of bodily degeneration, maintaining for years the balance between the processes of decay and repair.

The tendency to put on flesh after the age of forty is common to men and women of all races. This is due to the lessened nervous expenditure and lessened thyroid secretion, therefore resulting in a lessened rate of burning up of foodstuffs in the body. Unless the usual amount of food eaten in former years is curtailed too much flesh is gained.

The modern wise man who has reached what is called "old age" should have a diet chart made out for him by a physician who has carefully studied his habits and needs. Three dietary rules which might well be followed in old age are: First, to diminish the total quantity of food eaten; second, to take food frequently but in small quantities; and third, to eat only easily digested food which does not produce too large a residue of waste matter.

Regularity in diet is next in importance to decreasing the diet. Intervals between the taking of food should never exceed six hours.

The mayor of Crisfield, Missouri, has abolished the office of city health officer as a useless expense to the city.

# Physical Education in New York Rural Schools

BY DANIEL CHASE, SUPERVISOR OF PHYSICAL EDUCATION, STATE DEPARTMENT OF EDUCATION, ALBANY, N. Y.

NEW YORK was the first state to realize the need of the rural school child for supervised physical education and in 1916 enacted a statute providing for a program which should be compulsory in all the schools of the state. Before that time it was thought that children in rural districts received plenty of exercise in farm chores and in walking to school. It was overlooked that the small accessory muscles were little used in every day farm work and hence undeveloped in rural children. To meet this need and to offset awkwardness and heaviness the relief drills for country boys and girls were made lively rhythmic exercises involving movements which tended to develop the finer coordinations making for gracefulness, poise, and physical development.

It was also realized that the rural child distinctly needed supervised physical education to develop in him teamwork, loyalty, cooperation, for games and teams were new things to the child from isolated communities. The lessons of working with others learned on the playground would be a factor in making him a social being.

What New York state inaugurated, other states soon followed, and a year or so afterwards New Jersey, Nevada, Rhode Island, California, Maryland, and Delaware put on their statute books compulsory physical education laws and proceeded to enforce their programs. By the spring of 1921 a total of twenty-seven states had more or less effective legislation requiring the teaching of physical education.

The complete program of physical education involves four divisions: First, physical examination of all children; second, teaching of hygiene; third, order of exercises; fourth, social, moral, and health training on the playground and athletic field.

When the physical education law was enacted in 1916, the legislators thought it wise to insist that all districts have some assistance from specially trained teachers of physical education. The law was mandatory and in the first two years of its operation the district superintendents of schools were encouraged to engage special teachers or directors and put them in charge of the supervising of this work. It was then and is now the duty of the State Department's

staff to inspect, instruct, and supervise these specialists.

It was unfortunate that so many of these special teachers were not familiar with country school conditions and the problems of the rural teachers. It was more unfortunate that the trustees and patrons of the rural schools as well as the teachers themselves were not at all familiar with the full purposes of the program. Moreover, many of the special teachers were not fully trained in physical education and did not know how to supervise and help country teachers. The work of some of the well trained people was handicapped also and hindered in some sections by local opposition. Wherever the right spirit of cooperation among superintendents, teachers, and supervisors obtained, worth-while results followed, and in many sections the early opposition was overcome and the program put on a solid footing which still continues.

## Special Teachers Optional

A change in the law at the end of the second year made it optional for the small districts as to whether they should engage these special teachers or not but still required the same amount of instruction from the rural teachers and provided them some assistance from the State Department in the form of a staff of special instructors for rural schools. These instructors, eighteen in number, were assigned to definite sections of the state to work with the district superintendents.

During the last three years, rural teachers not having local supervisors have been required to attend four to six conferences each year at which they have been taught the requirements of the state syllabus and how to present the work to the children.

Under Section A of the Physical Education Syllabus and particularly in the part suggesting the formation of health clubs, this instruction has proved very effective. It was found in the 1921 survey of the state that 71 per cent of the one and two teacher schools had pupil health clubs organized. There has been a decided improvement in the amount of attention given to the daily as well as annual health inspection of country pupils.

Under Sections B, the daily relief

drills and setting up exercises were outlined for periods of five to six weeks at a time and carefully demonstrated and taught. Observations show that teachers themselves have profited greatly by this instruction. The improvement in posture, response to command, alertness, grace, and coordination on the part of the teachers who have attended these conferences and wholeheartedly taken the work has been marked.

Under Section C, talks on the teaching of hygiene and formation of health habits were given. The valuable bulletins on the teaching of health, issued by the Department of Education, Washington, D. C., were distributed and explained and other helpful literature supplied.

Under Section D, games were taught and methods of organization for play and team contests outlined and explained. Singing games and rhythmic exercises were given. As far as possible the attempt was made to impress the teachers with the educational value of this form of school activity. A particularly noteworthy bit of organization work was done in 1921 when the first State-Wide Physical Ability Test for Rural Schools was conducted. About five thousand schools succeeded in carrying out this contest. County championships were awarded in all but four of the counties and district championship certificates were given in one hundred and sixty-two supervisory districts of the state. It was a tremendous task and results were made possible only through the cooperation of the superintendents and the conscientious work of the county teachers. Play Festivals and Field Days were organized in larger numbers than ever before. In 1920 the State Staff organized and conducted eighty-eight such affairs and in 1921 nearly doubled that number.

But while New York has shown great progress in physical education, the present outlook is not so encouraging in spite of the excellent work. The New York legislature of 1921 failed to make provision for the retention of the state instructors to help the rural schools. While it is still possible for the districts to engage their local supervisors, and the state continues to pay one-half of the salary up to \$1,200, the law was so changed that schools with less than

twenty teachers are not required to have such help. Consequently, only a small percentage of the rural teachers have any special supervision or assistance this year.

Requests for help at conferences have been far in excess of the ability of the present staff to handle. There are but three men left where once were nine men and eighteen women. Many worth-while meetings have been held in which instructors from the normal schools and large villages have helped. Yet the conference program has been very inadequate. All schools have been supplied with a special rural syllabus on physical education. The staff has also prepared and sent to district superintendents a set of printed outlines of relief drills following plans used in the conferences, enough to supply the require-

ments of a school for a full year.

Many requests come for visitations and assistance which the staff is unable to comply with. However, extensive correspondence is maintained and suggestions as to health clubs, field days, exercise and play programs are being given. It is apparent that nearly all the conscientious teachers are doing their best to keep up the program for their pupils.

This year the small staff cannot give much time to the schools desirous of continuing the physical ability test. Printed matter is sent to superintendents who wish to conduct the test, and county and district championships are awarded to those superintendents who make reports.

Much valuable assistance is being given by agencies not definitely connected with the schools, interested in

promoting various phases of physical education.

The sections that have been enterprising enough to make plans engaging the visiting teachers are undoubtedly securing for their boys and girls a much larger share of the benefits contemplated by the physical education program than are the less favored districts. At present, not more than 20 per cent of the schools have such service. A larger extension of this plan is to be expected. It is clear that supervision is needed and will be needed until such time as all the teachers working in the country schools shall have been fully trained. The reorganization in rural school administration now being proposed by the committee of twenty-one may make the proper provision for this supervision.

## Camp Highlands, A Recreation Camp for Boys

**E**MPHASIS is being placed today on the fact that men and women in cities live under stress and strain which wears them nervously and physically producing various asthenias. Psychologists point to a return to more simpler ways of living in order to mitigate the evils of the present day system and are advocating the exercise of the more primitive brain areas, the larger muscles.

City children of the present day are not living the normal outdoor life that formerly in rural communities or small towns was possible. During the school year the boy is confined to the classroom a great part of the time. In summer the city holds little real recreation for him. To meet the needs of city boys who crave the chance to be freed from conventions and just be natural, Camp Highlands in northern Wisconsin was established. Here boys are given the opportunity to enjoy the sports their fathers enjoyed. They can camp, swim, row, paddle, play baseball, be with other boys. Dr. William J. Monilaw, medical director of the University School, University of Chicago, founded the camp in 1904.

A good camp comes nearer to furnishing a boy with a normal natural life than any other agent. Here he enjoys the companionship of boys and men; he learns to live by doing; he develops a strong and efficient body and a ready resourceful mind. He lives close to nature and delights in simplicity and freedom from convention.

In order that each boy be given an opportunity to compete with others his own age and strength, the camp is divided into three groups, senior, junior, and midget. These groups are again divided into teams so that boys of the same group are pitted against each other. Every boy is a member of a team and participation in at least a part of every game is compulsory.

In keeping with the spirit of freedom, the camp has few rules, the ones in force pertaining in most part to health and safety. Camp activities are managed by committees composed of three seniors, two juniors,

and one midget who are elected by the boys during camp assemblies. Two or more counselors usually act on the committees.

The order of the camp depends on the boys and much of the work is done by the boys themselves. They take turns waiting on table. Tents must be in perfect order by inspection time with the bed well made, floor swept, and all personal belongings in place. The clubhouse, boat-house, tennis courts, playhouse, and boats are cleaned daily and are inspected by the Officer of the Day.

Although much of the time is taken up with athletics and other activities,

The boys sleep in lodges and tents, five boys and a counselor in each.

Two swimming piers are maintained, one for the experienced swimmers in deep water and one on a shallow beach for beginners.

time is allowed the boys especially on Saturdays and Sundays to do as they please,—to develop initiative.

The health of the camp is guarded by the provision of a well rounded and well prepared diet, by a reasonable amount of play and athletics, by a limited time spent in the water, by open air sleeping and living, and by immediate attention by the camp physician in case of illness or accident. Besides the physician, the camp employs a nurse full time. The boys sleep in tents and lodges, five boys and a counselor to each. The tents of the three divisions are separated, all the seniors being together, the juniors, and the midgets each in its own group.

Equipment of the camp includes a large athletic field, a small play field, and five tennis courts. Two swimming piers are maintained, one in deep water for the experienced swimmers and one in shallow water with sloping sandy beach for the younger boys.

Situated on thirty acres of timbered lake front which it owns and occupying many other acres leased from the state, the camp is attractively situated. Other equipment of the camp includes a large two-story clubhouse, a kitchen and two dining rooms, bakery, ice-house, and cold-storage house, laundry, septic-tank toilet system, eleven large lodges, an infirmary with adequate medical equipment. The camp also raises its own vegetables; the boys care for the garden.

The urge for adventure, for following trails far inland is given outlet in the canoe trips up the various

streams through northern Wisconsin and across the line into Michigan. With broad, safe canoes, two boys and a counselor to each, camp equipment and food enough for several days, a party of canoes sets out. The trip takes them into wild and unsettled territory. Frequently deer come down to the water to drink. Shut in by an unbroken forest wall, the silence of the lakes is disturbed only by the weird call of the loon.

Camping and fishing trips to nearby lakes are also planned for the younger boys. Camp is made, tents pitched, meals cooked over a camp fire, balsam-bough beds prepared. The boys sometimes walk on these trips and at times cover twenty or thirty miles before returning to camp. Fishing is another sport enjoyed by the young campers. Aside from the nat-

ural sports enjoyed at camp and the athletic contests, occupations such as manual training and photography are provided for the boys. Tree and bird study clubs are formed with instructors in charge. In one season over one hundred varieties of birds have been seen and on the camp property twenty-six varieties of trees were discovered.

Target practice is another pastime at the camp. The boys are taught to handle a gun properly, to shoot in good form, and to care for the gun when through shooting. The regulation "one gun, one boy, and one counselor," provides for safety.

The camp usually has a band as well as a quartette or glee club. Discussion clubs to talk over live topics of the day are also formed.

The staff of the camp is composed of mature counselors, one to every five boys. Most of the men are high school or college teachers or men in the upper years of their college course. As most of the men return from year to year the personnel is an experienced one.

A parent's camp is maintained near the boys camp to accommodate visiting parents. Stay is limited to a day or two. The parent's camp serves also as a home for the families of married counselors.

From its own point of view the human race should have with respect to its follies and sins a "pay-as-you-enter" system. If the assessed punishment for each offense

Were to be paid in advance

I fancy there would be fewer offenses—T. K. H. in Chicago  
*Daily News.*

Target practice is a popular pastime. The boys are taught to handle a gun and to shoot in good form.

# A Survey of French Nurses' Training Schools

By KATHERINE M. OLMSTEAD, R.N., ASSOCIATE DIRECTOR, DIVISION OF NURSING, LEAGUE OF RED CROSS SOCIETIES, GENEVA, SWITZERLAND

ONE of the first visits I made in France was to see the nursing work being done by the American Commission for Devastated France which is under the direction of Mrs. Mary Breckenridge. An affiliation has been made with the Florence Nightingale Training School at Bordeaux, and many of these young well trained French nurses are now "carrying the bag" and doing excellent public health nursing work in the devastated regions.

Unless one has visited the area around Soissons, Reims, and the Aisne, one can scarcely appreciate the difficult, depressing work being so efficiently carried on by this small group of about twenty French, English and American nurses.

From the most wonderful green, fertile fields, filled with huge red poppies and bordered with poplars, one suddenly comes upon that section of France known as the devastated districts, a small portion of which still remains uncultivated and gives some idea of what large sections of the war-riddled fields were like at the close of the war. There are long stretches of ground where huge ragged holes and piles of stones and earth have been heaved up as if an earthquake had taken place. Much of it is covered with a mass of tangled, rusty, barbed wire, half hidden

under mounds of earth. The occasional pile of gray stone and the bare stumps of trees indicate where some home or village had been. Some of the villages where the nurses are working seem from a distance like mere piles of stones and cement with here and there a part of a wall or section of a church still standing, but upon actually arriving in each village we find many people living there, some have been able to build up the walls and put new roofs on their houses, some are still living huddled in basements under piles of ruins, while others are living in dugouts left by the German soldiers, but all are working hard to reclaim land and raise crops. This task has been both tremendous and dangerous. A nurse in one little village said that out of the forty-six men who were alive to return to their homes, eleven had been killed by unexploded bombs while endeavoring to clean up their fields ready for ploughing. Accidents of this kind are still happening. Swimmers are being caught and drowned in the rivers which are filled with barbed wire. There seems no place to put the rusty tangled piles of wire and it often forms a gruesome looking hedge along the once beautiful roadways.

In the most devastated villages or in the shadow of the remains of huge

cathedrals, everywhere one finds the results of the activities of the American Commission for Devastated France. Their small barracks are surrounded with children, men are hurrying away with books tucked under their arms and the women with a few cans of condensed milk or a layette for a new baby have contented, satisfied smiles on their faces.

Upon entering the barracks one finds a nurse busily engaged in weighing and measuring babies, advising mothers, and assisting the local French doctors whose return to these sections has often been made possible by the salaries offered by the Committee.

In another barrack a library is established and the worn looking books and the group of young people reading, especially on Sundays, testify that the libraries are appreciated. Classes in cookery, sewing, manual training, and the drilling of groups of boy scouts, make each barrack a real center of activity for health knowledge and recreation.

Some of the nurses have long distances to travel and have the use of a Ford car and a chauffeur. The chauffeurs are young women nearly all of whom are volunteering their time. They take the entire care of their cars and may be seen at certain hours each day at the central garages as they scramble out from under cars or hoods with clothes, faces, and hands black with grease and oil, but each with an independent air of one who keenly realizes that she is rendering a service well worth while. Some of the nurses in the larger towns ride bicycles. There is no lack of calls from doctors and patients, and the long visiting lists of each nurse and the number of visits made daily testify that her service is valuable and appreciated.

Undoubtedly critics of French nursing problems are correct who say the Bordeaux School for nurses is most excellent and that it is the only school in France which is graduating proficient nurses of an intelligent type with an all-round efficient training for nursing service. That these nurses are exceptionally efficient and are in great demand was recently proved by Mrs. Mary Breckenridge, director, American Commission for Devastated France, who, desiring to employ as

In the face of ruin and devastation France has realized as never before the necessity for training its women as nurses in times of peace as well as war.

The school for nurses being conducted by the Société de Secours aux Blessés Militaires was started twenty-two years ago to train volunteer nurses for the Red Cross.

public health nurses as many of these well trained French nurses as possible, sent questionnaires to all graduates of the school. When the answers had been received from almost all, it was found that, with but one or two exceptions, the graduates of this school were holding high and important positions to whom even the unusually high salaries offered by the committee and the interesting work made no appeal.

### Not Subsidiary to Hospital

Under the law of January 10, 1849, the Public Hospitals of Paris were separated from the church authorities and placed under the control of the newly organized Board of Charities. The problem of training and supplying nurses, not nuns, for the city hospitals was immense, and apparently a period of nursing decline resulted. In 1907 a central school for nurses was opened in the vast grounds of the Salpêtrière which also contains the Hospital for the Insane and the Home for the Aged.

The most surprising part of this school, L'Ecole des Infirmières de l'Assistance Publique, is the fact that its sole object was and still is to prepare women to undertake nursing as a profession. The city of Paris, evidently as early as 1907, realized a public responsibility for providing this type of training for French women, and built and equipped a school with most remarkable foresight and with all the care and knowledge which usually attends the development of universities and colleges, but to my knowledge has seldom, if ever before, been applied to a school for nurses. Even in Amer-

ica where we are tremendously proud of our advance in nursing education, we have never been able to develop a school for nurses which is not subsidiary to the hospital. Our schools exist too much in order to serve the hospitals, not primarily to educate nurses. We have, however, long realized that the future of our nursing education depends upon a change in the existing system. A start has been made in securing central schools for nurses where at least a part of the theoretical training of the students from various hospitals is given in a central educational institution. This system has recently been started in two or three American cities and is considered a most advanced step, even though the hospitals sending the pupils still depend upon student service for the care of their patients. We were, therefore, quite surprised to find in Paris a central school existing as an educational institution solely for the purpose of training nurses.

The normal duration of studies is two years but pupils whose professional instruction is considered insufficient at the end of the second year are authorized to continue at the school until satisfactory examinations for the certificates have been passed.

The matron, her assistant and five monitresses of the school, devote their entire time to the conducting of the school and helping the student nurses with their studies. The more advanced students are assigned to give a series of class lectures and demonstrations. The monitress who conducted us through the school explained that this was most valuable experience as the school hoped to

train in this way efficient head nurses and instructors for all the hospital wards where their students were receiving instruction. The French with whom we talked seemed to realize fully that, while the school, its buildings, its theoretical plan of training were most excellent, its weakness was in the low character of nursing work done in the wards of the hospitals where the actual bedside nursing was taught.

After visiting several of these hospitals, we realized why so much of the practical work was given at the school and why we were told frequently that the school hoped eventually to have its own graduates in charge of all wards. One could not help but be greatly impressed with the tremendous problem which the directors of the school are facing, and evidently much wisdom, judgment and foresight have been put into the developing of this plan for training professional nurses for France. While the general plan of the educational system seemed to us almost ideal, the weakness is of actual administration:

### Weakness of French System

First, the lack of good bedside nursing instruction, the teaching of finer technique which develops good careful nurses is entirely lacking. That this weakness is realized to some extent was manifested by the desire to get their recent graduates in charge of the wards, but even this change will not greatly improve the condition, as even they have not had the advantage of good instruction in nursing technique and have no idea what good bedside nursing care is. The second weakness was the lack of any educational requirements for entrance which results in a lowering of the intellectual status of the students entering and keeps young French women of ability and refinement from entering nursing. Without educational requirements nursing in France is placed on a plane where physical brawn is more important than intellectual ability, a plane deserted by the profession in America thirty years ago, because of its inefficiency.

No particular desire seemed to exist concerning educational requirements; no one seemed to realize that the absolute foundation of any advance in nursing rests on the ability to secure properly prepared and educated matrons and instructors of schools and hospital wards, and that teachers and leaders must be educated above the mass, in order to teach.

It seemed a great pity to us that some one or another of the Franco-American association working for better health and better care of the sick in France could not in some way get behind a school so efficiently organized and started by the French themselves, helping them to bolster up the two weaknesses which constantly debilitate nursing in France, first, by providing properly prepared instructors in bedside nursing until the school has its own supply and, secondly, by conducting a recruiting campaign of educational character which would advance nursing in France in the public mind to the height of a profession, thereby making it possible for women of intelligence to enter it. Most unfortunately, however, as Sir Napier Burnett recently said, Associations wishing to help France too often "build a machine and expect the spirit to get into it instead of using an existing machine and putting the spirit into it."

It is the usual thing to find in visiting the various activities started in Europe by outside countries the small well run unit revolving around itself and not carrying its methods or its improvements beyond its own walls.

The school for nurses being conducted by the Société Française de Secours aux Blessés Militaires was started twenty-two years ago for the purpose of training volunteer nurses for the Red Cross service. Ten years ago it was enlarged and remodeled,

Mlle. L. Geniry, directrice of the Hôpital Ecole de Société de Secours aux Blessés Militaires.

Operating room of the same hospital. Nurses in this school are of a refined, intelligent type. Very few go into nursing as a profession.

and since the war it has been painted and repaired, so that when we visited the school we thought it was a new building.

The nurses all seemed to be of the refined intelligent type and were most enthusiastic and interested in their work. Many of the fifty students now in training are taking the full two years' course to become either public health nurses, usually with some one of the tuberculosis clinics started by the Rockefeller Foundation or volunteer nurses in case of another need for Red Cross nursing service. Some few, but apparently not very many, go into nursing as a profession from this school.

### S. B. M. Conducts 70 Schools

The S. B. M. is conducting about seventy of these training schools throughout France where women enter, taking a simple or a superior course lasting from five months to two years according to the use they wish to make of the knowledge acquired. Much encouragement seems to be given for young women to take the full course, and the living and working conditions are made so attractive and pleasant that undoubtedly many remain. Many graduates of this school are doing excellent although isolated bits of public health nursing in France. One volunteer nurse was doing excellent school nursing in a public school as a demonstration in hopes that the city of Paris would later support and develop this type of work. We were surprised and pleased at the breadth of the social work and the knowledge and skill she showed in the detection of physical defects.

The most noticeable things about this school were the really intelligent

method of training used and the preparation and capability of the instructors and directrice of the school, the enthusiasm, intellect, and refinement of the students, and the general feeling that things were being well done and carefully done because the nurses loved to do it that way, not because they had to.

Bedside nursing was being taught in the school in quite an efficient manner but owing to the very small number of beds and the limitation of service, the actual bedside nursing experience obtained by the students is too meagre to allow of sufficient practice and the result is that the students are not trained bedside nurses. They seem quite well prepared, however, for specialized kinds of medical social service work by reason of large outpatient departments and public health and social experience available, and if the bedside nursing technique taught could be strengthened and made more comprehensive, an excellent group of public health nurses would be available.

We were very much interested to hear that L'Ecole de Puericulture de la Faculté de Médecine de Paris had received 500,000 francs from the Junior Red Cross of America on condition of their raising a similar amount in France. The school is only one year and three months old and is now conducted in a series of barracks. They hope to put up a permanent building later on. Its purpose was not to treat sick children but to keep well children healthy. Over two thousand babies were being cared for through this station.

Nurses enter this school from the Red Cross hospital schools for a three months' course. Another course of one year's duration is given to which

only graduate nurses are eligible and for which a diploma from the University of Paris is given.

We were interested in the physical culture work being done at the Association des Dames Françaises. When we first entered the building we saw many little children running around in attractive gray and white Roman costumes and, upon inquiry, we found the class in physical culture was being conducted in the building, owing to the bad weather. A very capable looking director was in charge of this work. A large outpatient department is run in connection with the school and the association also conducts a summer camp where 500 children are cared for each year.

The school for the training of nurses was a very well equipped, clean building. Twenty students were in training and the length of the course evidently varies with the type of work which the graduates wish to do, from five months to two years being required.

The outpatient department and the operating room service seemed well developed giving a fair training to the students, but here again the bedside nursing service was meagre.

#### Home for War Orphans

We were anxious to see how France was caring for war orphans so Mademoiselle de Haussonville took us to the Orphelinat de la Cantoria where we found about forty boys being cared for by Monsieur Jules Meunier, a musician. A large old house had been given over to the orphans. The school seemed to be run on the self government plan and the boys were extremely well behaved, happy, contented, and very much interested in the music and the large garden which they were caring for. They were poorly clad, the place was meagrely furnished, but a splendid spirit existed, the older boys evidently sharing in the care and teaching of the younger children.

Miss Crowell of the Rockefeller Foundation for the Prevention of Tuberculosis in France arranged most interesting trips and made it possible for us to visit about eight of the tuberculosis dispensaries started by the Foundation some of which had already been turned over to the French.

The dispensaries are all admirably and most completely equipped, each with a laboratory, a dental room, general examining room, large waiting rooms and room for records, and complete radiographic service.

The record system is the same in

all the clinics and seemed most excellent, being very complete. The history cards of the entire family are kept in one envelope and different colored cards are used to signify children, stage of disease, etc.

We were very much impressed with the type and appearance of the French women in charge of the various clinics. They were most interested, intelligent, and capable, and were undoubtedly doing very good tuberculosis dispensary work. The clinics were well cared for, the records neat and full, and the patients carefully looked after and efficiently handled. We noticed the nurses doing many thoughtful things to make them more comfortable during the examination which showed good training and a high degree of personal intelligence and interest.

The social work of the Health Visitors, as they are called, seemed excellent and thorough. We were impressed favorably by the apparently good clinic and social work they are doing.

The above accounts are mostly concerned with the interesting and well carried out activities which we saw in Paris. We visited several other hospitals where the buildings were splendidly equipped for the care of patients, but nursing technique was entirely lacking, or so poorly done it was quite too horrible to describe.

We saw many small but very excellent pieces of public health work being done by the French themselves, in all of which we were impressed with the apparent farsightedness and the great care for details and thoroughness with which they were being developed.

We saw much of the very worst nursing and some few bits of the best nursing we have ever seen. We saw some excellent plans for the training of nurses, each lacking, however, one or two essentials which prevent a production of truly efficient well-trained nurses. We felt that while there was undoubtedly much to criticize in the nursing situation in France, there existed a few small and perhaps greatly overshadowed pieces of nursing work which we might well praise and which we hope will in time develop to such an extent that the general nursing service will be greatly improved.

We could not help but be impressed with the fact that many of the hospitals were not even partially filled, whole wards were frequently empty, but the outpatient departments were well equipped and were always crowded. Much of this may be due

to the very poor nursing and the consequent dislike by the people for hospital care.

We decided that nursing as nursing was not disliked by the best type of French women, but that nursing as a vocation other than that connected with dispensaries or social service work was looked down upon and not understood as necessary for public welfare. We felt that volunteers are receiving a far better training than professional nurses and that many of these volunteers are extremely interested in doing various types of public health and social nursing, and are doing it extremely well.

The various lines of public health nursing, if stimulated properly, would and could undoubtedly cause these schools for volunteers to change into schools for public health nurses, and eventually France would have a group of well trained, capable women in the nursing profession, who could gradually tear down tradition and over-balance the great number of poorly trained ignorant women now so typical of France's professional nursing staff.

#### Predominating Defects in the Pre-School Age

The examinations of 1,061 prospective entrants into the public schools of New York City, made in their special study of the physical and mental condition of children of the pre-school age, corroborates earlier experience as regards the need of intensive correction of remediable physical defects among children of pre-school age. The children were mainly between five and six years of age. Only 33.3 per cent were found normal; 66.7 per cent had physical defects. Of the latter group, 25.2 per cent were children who had defective teeth as the only defect found; the remainder had one or more physical handicaps with or without teeth defects. The proportion of abnormalities was about the same for both sexes.

The predominating defects discovered, outside of teeth, were hypertrophied tonsils, 26.3 per cent; defective nasal breathing, 23.1 per cent; and malnutrition, 19.2 per cent. The incidence of each of these defects is greater among the children of pre-school age than among school children. Findings of this character forcefully urge the addition of an important link in the chain of child health supervision; with the correction of such defects the first step in preventive medicine will have been taken.

# Boy-Building Is Business of Camp Roosevelt

BY MAJOR F. L. BEALS, COMMANDANT, CHICAGO, ILL.

IF THE boys of America could spend a few weeks each summer in an out-door camp, the health of the nation at large would be vastly improved, and the pitfalls of leisure which now beset American boys and provide one of the baffling problems of society would be at least partly eliminated. If recreation is necessary for men and women, how much more necessary it is for the growing boy penned up for the greater part of the year in the school-room and partially denied the inalienable privilege of boy-hood,—play. The desire to provide the boys of the whole United States with a great summer playground actuated the founding of Camp Roosevelt. Peter A. Mortenson, Superintendent of Chicago public schools, approved so thoroughly of the plan as I outlined it to him that he gave his unqualified support to the project and made the camp an auxiliary of the Chicago summer school system.

The Camp Roosevelt Association has been fortunate in securing a tract of about two hundred and fifty acres, near LaPorte, Ind., upon which had been erected and in use for several years the buildings and equipment of a boys' school, including a gymnasium, mess hall seating one thousand, kitchens, electric power plant, deep well, modern sewage system, large hospital, classroom buildings, bungalows, dormitories, and recreation rooms. Included and surrounded by the tract is Silver Lake, about eighty acres in extent, with sandy beaches and diving platform. Large fields provide for tentage, sports of all kinds, and parade ground. The ground is rolling, well wooded and drained, and the surrounding country affords opportunity for hikes in every direction. With the beckoning pine woods, the alluring waters of beautiful Silver Lake, the camp site offers splendid facilities for the vacation pastimes that boys love.

It is restful just to visit Camp Roosevelt for a day, but to have the privilege of living there during one of the camp periods and to share in all of the fun of the camp and camp life is a prospect that might make even the satisfied individual crowned with the success of middle life anxious to turn back the clock a decade or two in order to join the boys in their play.

Camp Roosevelt, however, was not intended entirely as a play camp. An important work is going on, interwoven in the play, the physical training and the school course, that of boy building. Camp Roosevelt aims to build better boys, mentally and morally, as well as physically. It aims to provide not merely an ordinary summer's diversion for the boy, but a real agency for character building on a solid foundation. One of the first essentials toward elevating the character in its formative stage is to bring the boy out in the open, next to nature, living under the stars and breathing the pure, fresh air. With that as a background, the work of boy-building can be done in earnest.

## Varied Activities of Camp

The steps which must be taken to bring about the final results are many and varied. With a program of physical exercises, drill, guard duty, athletics, each different phase of character building can be awakened to life. The physical activities build up the strength and virility of the boy. Guard duty and military drill instil those attributes of precision, alertness, and cleanliness which make for a keener, more intelligent manhood. Contact with hundreds of boys, each one trying to live up to the high standards set by the men under whose leadership he is placed, brings out self-confidence and overcomes self-

consciousness, which in later life is one of the greatest business requisites. This is vastly important in the correct training of the boy.

The life of the boys is a life of simplicity and wholesome environment. The boys are quartered in large pyramidal army tents, without flooring, and well ventilated. Army cots and blankets are also supplied. The boys bring their own clothing and toilet articles, all of which are inspected by the company officers at least once a week. In this connection, it might be said that the chief insistence in the matter of equipment is the simplicity of arrangements. Elaborate bedding, superfluous blankets, excess toilet facilities, and all other unnecessary impediments of camp life are eliminated.

Because of this freedom from fold-rol, the cost of the camp to the boy is very small. This boy-building project would not fulfill the purpose for which it was intended were it to cater to but a select few. In order to make it easily accessible to boys from all walks and stations of life, it has been placed on a philanthropic basis. This does not mean that it is a charitable institution, but the expense is mainly borne by public-spirited business men of Chicago. Mr. Angus S. Hibbard, former vice-president and general manager of the Bell Telephone Company, is chairman of the Camp Roosevelt Association, which handles all financial matters.

Under the direction of Major Shields of the American Red Cross, national headquarters, every boy in camp is given a course in first aid instruction.

Sandy beaches surrounding Silver Lake afford excellent bathing facilities. The prone-pressure method of resuscitation is part of the first aid training the boys receive.

The boys themselves pay such a very nominal fee that it is within reach of even the penniless boy who can easily earn the needed sum by a few weeks of hard work after school hours.

One of the major benefits of the camp is democracy encouraged by the military life and discipline. The favored boy and the under-privileged lad have the same favors and the same privileges. The khaki uniform makes all boys equal, and every youngster stands forth on his own merits.

The health of every boy in camp is carefully safeguarded. A large splendidly equipped hospital is maintained by the First Aid Chapter of the American Red Cross of Chicago under the direct supervision of Dr. H. W. Gentles. The National Red Cross organization of Washington, D. C., details Major M. J. Shields as the senior surgeon. Under his direction are three physicians and two nurses, who, in addition to watching over the general health and sanitation of the camp, teach the boys how to apply first aid and emergency measures. Every boy in camp is obliged to take a course in Red Cross instruction. Those who realize the magnitude of this instruction in first aid alone can appreciate the wholesome influence upon the community of this one branch of activity at the camp.

The general health rules which are fully observed preclude any serious difficulties. Sunburn and blistered feet are practically the most dangerous troubles brought to the attention of the medical staff. Frequent foot

inspection is held to prevent any serious foot trouble or infection. A thoroughly up-to-date dental dispensary is maintained by representatives of the Public Service Committee of the Chicago Dental Society, Dr. Dan U. Cameron being the inspiration behind this unique move. The teeth of the boys are carefully examined, many defects corrected, and cavities filled. Toothbrush drill is one of the daily activities of the camp.

One other point, and one which has a distinct bearing on the health of

the camp, is the matter of morale. The healthy camp must have a healthy moral tone, and this is again particularly true with reference to a camp for boys. For this purpose, the Y. M. C. A. maintains a "Y" hut and a corps of secretaries whose province is the general comfort and well-being of all of the boys in camp. Moving pictures, music, speakers, entertainments, books, stationery, laundry service, and the like, are all helpful forms of service supplied by the "Y" secretaries.

The camp aims to live up to the standards of rugged manhood exemplified by the man for whom it was named. It teaches the boy to be democratic, to have community spirit, to develop individuality. Every boy is the stronger for having spent a few weeks at Camp Roosevelt and the gain of the city and state is commensurate. The camp gives many boys their first taste of real out-door life.

Camp Roosevelt is open to any healthy, clean American boy twelve years of age and over. The season is divided into two periods of three weeks each. A boy may attend either one or both of these periods. The headquarters for the camp is at the Chicago Board of Education, 460 South State Street. In the interests of building better boys, it would seem that all who become acquainted with the Camp Roosevelt idea should interest themselves in it, for it bespeaks for the future of our country a better citizenship.

General health and sanitation of the camp is carefully guarded as is that of the individual. Physical examinations are made of every boy in camp.

## Calcium and Experimental Rickets

The effects of low calcium content in a diet fed to rats, which contains a sufficient supply of fat soluble A, and has an approximately normal content of phosphate, is the development of a pathological condition of the bone which has certain fundamental resemblances to human rickets. In a series of experiments conducted by McCollum, Simmonds, Shipley and Park of the Johns Hopkins University and reported in the *American Journal of Hygiene* of July, 1921, it was discovered that this ricket-like condition of the skeleton does not develop if the deficiency in calcium is compensated for by the addition to the diet of calcium carbonate or if the animal is allowed to receive cod liver oil. Administration of cod liver oil is followed by the healing of the lesion formed by the calcium deficiency. Butter fat, even in liberal amounts, fails to prevent injury due to calcium deficiency. These results suggest the possibility that a dietary essentially distinct from fat-soluble A may exist; this substance being present in butter fat in small amounts, but abundant in cod liver oil.

## American Children in the Tropics

A study has recently been made of the problems and difficulties of rearing children in the tropics, where the climatic conditions are marked by great heat and humidity where diseases peculiar to the tropics are prevalent; where the mortality among Chinese infants and children is high, and smallpox is deadly and malaria is universal. Malaria if not fatal, leaves its victims more or less impaired and the milk supply is entirely unsatisfactory and nutritional disturbances cause many deaths. In spite of these unfavorable climatic conditions some sixteen children born to American missionaries in China are alive and healthy today.

The missionary, before he goes out into the field, is required to pass a physical examination. He has no latent diseases and is in good condition. As a rule there is a physician in each of the mission stations and the intelligent co-operation of mothers helps greatly in environmental as well as dietary conditions. The hereditary and environmental factors then, are as satisfactory as possible under the circumstances, and medical advice and attention is available.

The economic and industrial expansion of the United States is requiring that more and more men and women take their families to the tropics, so that the problem of rearing children under such conditions are of necessary interest. The author, who writes of conditions in China in the *Journal of the American Medical Association* of June 11 concludes that healthy American children can be reared in the tropics and that there is no need to hesitate because

of climatic conditions if attention is given to housing facilities; ceaseless vigilance and co-operation with the physician concerning dietary and sanitary matters on the part of the mother, immediate medical facilities, and sufficient changes from the heat into a cooler climate. The problem of childbearing makes the responsibility of the mother particularly important through the nursing period, especially if there is difficulty of feeding.

## Japan Looks to the Future

THE Japanese Government is making efforts to improve the physical development of the rising generation. The daily physical exercises required of the children in public schools are far more exacting than anything of the kind in America. Bodily ventilation and sunlight are doing their dual corrective work for these children.

The problem of the children is urgent in Japan as in other countries, and the people are becoming aroused to a new sense of responsibility for their care. Measures are being considered for the correction of any weakness due to racial or other habits, according to the *Japan Advertiser*, and sanitary and health bulletins are being used for educational propaganda.

In his studies on ventilation and efficiency Leonard Hill commends the Japanese for their slightly built

dwelling heated in cold weather only by charcoal braziers for warming the hands. Clothes and exercise rather than excess artificial heat are depended on to keep the body warm. This is in sharp contrast to the practice of Europeans and Americans during the last century or so, of building draughtless houses and securing inside by artificial heating a climate, tropical in temperature, and parchingly arid. Instead of the body being kept warm naturally by the stimulation of cool air, exciting muscular exercise and glandular activity and so enhancing combustion of food, it is kept warm by the blanketing effect of warm, stagnant air, so that sedentary occupations may be carried on, and amusements of rest taken with a minimum of open air exercise. It is in the impulsion to activity and the raising of metabolism that open air life owes its beneficial effect.

The theory of bodily ventilation finds favor in Japan. A new department in Japanese school practice is the open air school in which children wear the minimum of clothing.

# Why the Arch Preserver Shoe Preserves Foot Health

**T**HREE things explain why the Arch Preserver Shoe preserves foot health.

First, the lasts are designed so that the inside of the shoe will be **exactly** like the foot. The design takes into consideration the fact that in the foot there is a **transverse** as well as a lengthwise arch; also that the foot was planned to walk on a flat surface.

Second, the construction of the Arch Preserver Shoe is such as to provide the full length walking base Nature planned. The foot in an Arch Preserver Shoe is supported **exactly** as if it were bare and flat on the floor. This is due to the concealed built-in arch bridge. It gives firm support at all three of the weight contact points, the heel, the outside and the ball.

Third, the Arch Preserver Shoe is fitted **from heel to ball**, thus insuring the placing of the foot in the shoe exactly as the last was placed.

These three things enable you to understand why a woman wearing the Arch Preserver Shoe enjoys "barefoot" comfort at all times. The built-in arch makes it possible to have this comfort and at the same time good style shoes.

The results which so many thousands of women declare are "miraculous" are only logical, and due to the fact that these women have, for the first time, given their feet correct support, in properly designed shoes, correctly fitted. Write for booklet 54 on foot health.

**THE SELBY SHOE COMPANY**  
44 Gallia Street PORTSMOUTH, OHIO

Nature plans that the foot rest on heel, ball and outside arch.

Civilization demands that heel and arch be raised.

The Arch Preserver Shoe with its built-in Arch satisfies both Civilization and Nature.

**A**RCH Preserver Boots and Low Cuts are made for women and misses in all styles, and widths, AAAA to E. Sold by 2,000 dealers.

This trade mark appears on the sole and lining of all Arch Preserver Shoes!

# The Atmosphere and Man

THE Division of Biology and Agriculture of the National Research Council has come to the conclusion that the study of the effects of the atmosphere ought to stand on a par with the study of the effects of nutrition and of bacteria and other parasitic causes of disease. It believes that these three environmental conditions include practically all of the environmental as opposed to the hereditary causes of disease. Inasmuch as atmospheric influences have been studied far less than those of food and parasites, the National Research Council has appointed a Committee on the Atmosphere and Man. The object of this Committee is to study all sorts of atmospheric influences including the effects of climate and weather, acclimatization, the effect of tropical conditions upon resistance to disease, the relation of clothing and ventilation to health and efficiency, and especially the specific effect of all sorts of combinations of atmospheric conditions upon the various organs and physical functions and upon persons of various ages, races, sexes, occupations. Detailed observations will be conducted over a period of twenty-five years in Detroit and in New York City.

Up to the present three sub-committees have been organized, namely, on the Atmosphere and Mortality, on the Industrial Effects of the Atmosphere, and on Experiments. The work of the Sub-Committee on Mortality is already under way with the cooperation of the New York Department of Health, the New York Life Insurance Company, the Metropolitan Life Insurance Company, and the Board of Health of Detroit. The Sub-Committee on Industrial Effects has received promises of cooperation from a number of factories. The Sub-committee on Experiments is cooperating with the United States Public Health Service, the United States Bureau of Mines, and the American Society of Heating and Ventilating Engineers. As yet the Committee is not ready to announce further plans. It is especially desirous of entering into intimate relations with all agencies that are engaged in studying allied subjects for the purpose of correlating and extending such studies.

The membership of the Committee and Sub-committee is as follows:

*Committee on the Atmosphere and Man.*—Ellsworth Huntington, chairman, Yale University, New Haven,

Conn.; Louis I. Dublin, Metropolitan Life Insurance Company, New York City; J. Arthur Harris, Section for Experimental Evolution, Cold Spring Harbor, N. Y.; Yandell Henderson, Yale University, New Haven, Conn.; Arthur Hunter, New York Life Insurance Company, New York City; Burton E. Livingston, Johns Hopkins University, Baltimore, Md.; Charles F. Marvin, United States Weather Bureau, Washington, D. C.; Raymond Pearl, Johns Hopkins University, Baltimore, Md.; Leonard Hill, Medical Research Committee, London, England; Frederick L. Hoffman, Prudential Life Insurance Company, Newark, N. J.; William H. Howell, Johns Hopkins University, Baltimore, Md.; Beardsley Ruml, Carnegie Corporation, New York City; J. W. Schereschewsky, United States Public Health Service, Washington, D. C.; Frankwood E. Williams, National Committee for Mental Hygiene, New York City.

*Subcommittee on the Industrial Effects of the Atmosphere.*—Ellsworth Huntington, chairman, Yale University, New Haven, Conn.; R. H. Lans-

burgh, University of Pennsylvania, Philadelphia, Pa.; F. S. Lee, Columbia University, New York City; Leonard Outhwaite, Personnel Research Federation, New York City; A. H. Ryan, Scovill Manufacturing Company, Waterbury, Conn.; S. S. Sayers, United States Bureau of Mines, Washington, D. C.; L. R. Thompson, United States Public Health Service, Washington, D. C.

*Subcommittee on Experiments.*—William H. Howell, chairman, Johns Hopkins University, Baltimore, Md.; Yandell Henderson, Yale University, New Haven, Conn.; E. C. Schneider, Wesleyan University, Middletown, Conn.

*Subcommittee on the Atmosphere and Mortality.*—Ellsworth Huntington, chairman, Yale University, New Haven, Conn.; Louis I. Dublin, Metropolitan Life Insurance Company, New York City; J. Arthur Harris, Station for Experimental Evolution, Cold Spring Harbor, N. Y.; Frederick L. Hoffman, Prudential Life Insurance Company, Newark, N. J.; Arthur Hunter, New York Life Insurance Company, New York City; G. T. Palmer, Board of Health, Detroit, Mich.; Raymond Pearl, Johns Hopkins University, Baltimore, Md.

## Methodist Hospital Conference

THE Fourth Annual Meeting of the National Methodist Hospitals and Homes Association was held in Chicago, February 15 and 16. The association is made up of representatives from 72 hospitals, 43 children's homes, 35 homes for the aged, 5 working girls' homes, 1 young men's home, and 1 home for retired ministers, all managed by the church. Doctors, nurses, and superintendents of the institutions were in attendance.

That the hospital is being reorganized as a workshop with facilities representing the last word in scientific medicine and workers representing the best in training and skill was the statement of Dr. Willard C. Stoner, Director of Medicine at St. Luke's Hospital, Cleveland, Ohio, who read a paper on "The Hospital Problem in Relation to Modern Medicine." The establishment of hospital facilities in rural communities would be the rational solution of medical practice in these districts, he thinks.

Dr. Stoner's emphasis on the importance of amplifying hospital facilities, of making the hospital a complete workshop in order that medicine may

be marketed to the public at a price which is not prohibitive, as contrasted with the private cooperative clinic established on a commercial basis, was based on a general survey of hospital organizations such as represents the organization of St. Luke's Hospital, Cleveland, Ohio.

The great need of medical missionaries who will go into rural sections and build up the health of the people was stressed by Rev. C. M. McConnell of Chicago who gave comparisons of the health of the 12,000,000 rural school children and the 12,000,000 who attend city schools, demonstrating that those in the city are taken care of much better than the school children of the country. He also urged the need of the visiting nurse to visit the homes and teach people how to live and what to eat, thereby avoiding the common diseases. An emergency hospital in country districts with nurses and modern equipment, such as is being built at Pittman Center, Tenn., will solve in some measure the rural problem.

In discussing nurse problems, Dr. C. S. Woods, Indianapolis, Ind., urged

## Metatarsalgia and Callouses Caused by Weakened Transverse Arch

This condition is recognized by depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is described by Whitman as Morton's Toe.

These conditions, Doctor, are quickly relieved and permanently corrected by the use of

### *Dr Scholl's* *Corrective Foot Appliances*

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. Different types to meet all emergencies.

Sold and fitted by leading shoe dealers in

every community who have been instructed in Anatomy of the foot and how to properly apply correctives to the foot and shoe.

Important pamphlet, "*Foot Weakness and Correction for the Physician*," mailed upon request.

**THE SCHOLL MFG. CO., 213 West Schiller Street, Chicago**

the nurse's helper as a partial solution for the shortage of nurses. Such a helper would do some of the routine work, giving the nurse more time for her studies and practical experience in nursing which is to fit her for later service.

The following officers were elected: President, E. S. Gilmore, Superintendent, Wesley Memorial Hospital, Chicago; First Vice President, and Chairman of Publicity Committee, S. W. Robinson, Executive Secretary, Methodist Homes for Children, Williamsville, N. Y.; Second Vice-President and Chairman of Finance Com-

mittee, J. A. Diekmann, Superintendent, Bethesda Deaconess Hospital Association, Cincinnati; Third Vice-President and Chairman of Nurses Training Committee, Miss Blanche M. Fuller, Superintendent, Methodist Hospital, Omaha, Neb.; Fourth Vice-President and Chairman of Committee on Homes, W. H. Underwood, Superintendent, Crowell Memorial Home for Aged, Blair, Neb.; Treasurer, Mrs. W. S. Phillips, Superintendent, Methodist Home for Aged; Secretary, W. J. Jordan, Executive Secretary, Asbury Deaconess Hospital, Minneapolis, Minn.

## School of Hygiene Endowed

**T**HE gift of six million dollars by the Rockefeller Foundation to the Johns Hopkins University School of Hygiene and Public Health will provide a permanent endowment for the School and will make possible the erection of the new building for the school on a site adjacent to the Johns Hopkins Medical School and Hospital.

Since the opening of the school in 1918, the Foundation has furnished funds for its maintenance from year to year, but with the acceptance of the present gift the trustees of the university assume full responsibility for the future needs of the school.

This is the second school of public health that the Rockefeller Foundation has materially aided recently. Its gift of two and a quarter million to the Harvard University School of Public Health last summer made possible the reorganization of an insti-

tution already established with other funds.

The special province of the school of public health is the improvement of personal and public hygiene, the warding off of epidemics, the constant battle against bacilli which not only destroy human life but also cause later chronic ailments.

In preventing disease other sciences than medical are required. In promoting public health, the sanitary engineer, the laboratory scientist, the inspector of foods, the epidemiologist, the industrial physician, the administrator, the educator, and the public health nurse are called upon as well as the medical practitioner. Schools of public health give instruction to physicians and others who engage in these various health activities. By research and field demonstrations they constantly add to the knowledge of

the science of hygiene and promote its wider practice.

The new type of institution places emphasis upon the development of preventive medicine and upon the training of health officers. Under the direction of Dr. William H. Welch the School at Johns Hopkins has made substantial progress in the four years since its establishment. Twenty-seven states and ten foreign countries are now represented in the student body numbering 131. The faculty of the school comprises scientists in the fields of bacteriology and immunology, sanitary engineering, chemical hygiene, physiological hygiene, medical zoölogy, epidemiology, vital statistics, and public health administration.

Regular courses of study lead to the degrees of Doctor of Public Health, Doctor of Science in Hygiene, and Bachelor of Science in Hygiene. A certificate in public health is given to those completing certain special courses. Short courses or institutes are provided for health workers in service who cannot be absent from their positions for more than a few weeks at a time. Last year thirty-six health officers from eight states took these short intensive courses.

## Hotel Furnishes Scientific Diet to Guests

The Waldorf-Astoria Hotel, New York City, is pioneering in the field of furnishing scientific diets to guests suffering from nutritional disorders. Seven menus have been prepared by the hotel dietitian on the advice of a medical consultant to serve in a general way the needs of guests. The menus include:

No. 1, high cellulose diet for constipation, atomic and intestinal toxemia; No. 2, high cellulose, low calory to reduce weight; No. 3, low sugar and starch, high protein and cellulose for poor sugar tolerance; No. 4, low cellulose, low condiments for acute ulcer cases; No. 5, low cellulose, high calory, high fat—a diet of simple, nutritious, non-irritating foods; No. 6, low purin for arterio-sclerosis, advanced age, and angina pectoris; No. 7, low purin, for rheumatism and neuritis.

The No. 5 menu is the diet for children. For convalescence, malnutrition, colitis, and underweight.

The menus are not supposed to fit individual cases and warning is printed on the back of each enjoining the advice of a physician. This is the first attempt of a hotel to furnish a scientific diet service.

## How the Right Shoes Increased Her Sales

*A true story with a lesson for all men and women*

"MISS GREEN, you and eight other girls out of seven hundred have shown increased sales during the last three months. All the others show losses. Why have you been able to increase your sales?"

"Who are the eight girls?" asked the young woman.

The president of the store read the names. The girl seemed happy to answer:

"Shoes—Cantilever Shoes. I got them first. Later I took each of those girls, in turn, to the Cantilever Shop. In Cantilevers, you see, our minds are off our feet. The business gets all our attention. We don't feel cross, cranky or tired. I suppose that's why our sales are good."

That afternoon the president of the big store walked into the Cantilever Shop and asked a salesman to explain the features of Cantilever Shoes.

The Cantilever salesman took a shoe and bent the sole at the shank, showing how the shoe

conforms to the human foot, even to having a flexible arch like the foot. He said, "the arch of the foot should flex with every step, according to nature, yet ordinary shoes are made rigid by a concealed metal shank-piece that forbids free movement of the shank-piece. There is no rigid shank in Cantilevers. The 'waist' is designed to lug the instep, the shoe fits and supports the arch restfully. The flexibility allows the arch muscles free play and this, together with the natural lines of the shoe, permits perfect circulation.

"It is important to allow the foot muscles to exercise, to keep well and strong. The forepart of a Cantilever Shoe is shaped to look well, while allowing the toes to lie in their normal position. Cantilever heels are moderately high—high enough to be smart, without throwing the posture of the body out of balance as exaggerated heels do, causing unnatural pressure and strain on the nerves and the internal organs. By wearing Cantilever Shoes a woman avoids headaches and backaches, irritability and nervousness. She is brighter and happier."

"The subject is of great importance to the business woman who is required to stand during the greater part of the working period. The tired feeling often complained of at the end of the day's work may be attributed to ill-fitting shoes."

—Dr. Wilmer Krusen, head of the Department of Public Health of Philadelphia.

"Pain is a great foe to good looks. Comfort works just the other way. If you are comfortable, you are apt to be pleasant, and pleasantness and prettiness are often synonymous terms. Eliminate as many of your worries as you conveniently can—and your tight shoes."

—Grace Margaret Gould on "Good Looks" in Woman's Home Companion.

"Working women are the worst offenders. It is the girls who are on their feet most who persist in wearing the highest heels. Sensible women have learned that they can increase their efficiency and even earn bigger salaries by wearing shoes built for solid comfort and health."

—Dr. Evangeline W. Young, of Boston.

## Glands and Personality

THE human organism as a going concern has received less attention from scientists than has the consideration of isolated organs or functions and confusion has resulted from the fact that the findings brought out in detached and over-elaborated studies of mind, of metabolism, or of physical processes, though interesting and illuminative, fail to dovetail when all reports are in. Notwithstanding apparent contradictions, however, we have been prone to accept the objective findings of the laboratory and even to a marked degree to credit the speculative constructions of human behavior as devised in the field of psychology in the hope that finally a complete and sufficient explanation of man as an entity would evolve. We have been inclined to accept these isolated facts as truth and rather to discredit more complete "systems" because the more symmetrical stories of human origin and trend have one by one soon come into disrepute. Dualism theoretically explained the diverse mental phenomena, but now pure science will have none of it, and Spencer's one way evolution with inevitable improvement of types has been entirely discredited.

Fascinating possibilities, however, are suggested by the thesis of Louis Berman in "The Glands Regulating Personality." In this book an elaborate but precise category is created for every personality; he takes care of every trend, accounts for exceptions, and aberrations, provides for control, and opens a wide vista of further development. The explanation of constancy as well as diversity of types he finds in chemical formulae of glandular stimulations and inhibitions, the whole process of life being under the control of the hierarchy of the hormones. Specific organization is constant under the domination of a given gland. "There is an endocrine aspect to every activity, normal and abnormal, internal process and its external expression." The physiology of natural ability becomes, according to Berman, fundamentally more important than mental tests. Personnel may be chosen on this basis. Financiers and musicians are pituitary types; thyroid domination produces superabundant energy; and adrenal types are unfit for sustained effort. Moral codes become subject to remedy through the sanitarium treatment of the thymocentric, it being as futile to expect these

individuals to improve on admonition any more than we can expect a typhoid patient to obey a request to "please do not develop a temperature of 99 degrees in the morning." According to this theory an extension of Kimball's wholesale feeding of iodine to avert thyroid deficiency is in effect an effort to raise the general mental level of the community and man can conceivably govern his future development through the control of his endocrine constitution. But the matter is not so simple. Glandular imbalance is not subject to precise regulation, nor is its nature and degree at present to be reduced to a mathematic index. The first organic reac-

tion to environment was undoubtedly a chemical response, and chemical it must remain, but even now another school of thought is busy explaining everything on the basis of the electrical nature of man. We always make a mental reservation when a single explanation is offered for human complexity. The book of Berman, however, is a distinct contribution. He has been an indefatigable reader and synthesizes practically everything that is sound in physiological research. His ideas tumble out in such profusion as often to confuse his style—even to sacrifice grammatical construction—but the whole work is stimulating and of intense interest.

The Macmillan Company, New York, 1921.

## Monitor Ventilation System

THE advantages of monitor ventilation over plenum or other systems are reported by Walter A. Griffin, M.D., Sharon, Mass., in the *Boston Medical and Surgical Journal*. There is nothing new about monitor ventilation, the Indian wigwam built in the shape of a cone with its apex open for the escape of smoke being one of its oldest examples. Nearly all railway coaches are ventilated by this system as are barns of the old-fashioned cupola type.

The monitor system is rarely used, however, in halls, theaters, schools, and hospitals, and little seems to be known of its possibilities in these connections. In fact this system as used in the Children's ward of the Sharon Sanatorium has excited much comment from physicians and laymen alike.

The fundamental requirement of ventilation is that it should keep body heat and humidity below a certain level so that good ventilation means practically good heat elimination. It is a matter of common knowledge that vitiated air tends to rise, and in case of fire instructions are to keep near the ground floor to avoid suffocation.

In Massachusetts the law provides only for plenum ventilation or some modification of this system. The statute requires that there shall be outlets near the floor which shall insure the removal of two and one-half cubic feet of air per minute for each foot of the room; that there shall be "inlets" for pure air equal to the amount removed and at such height from the floor as to "insure proper circulation."

If the room is to be used as a school, the air may be supplied by pressure through the floor and the outlet may be through grills in the ceiling. The efficacy of the plenum system was tested at the Massachusetts Hospital school in Canton some years ago by the superintendent, Dr. John E. Fish. Certain rooms thoroughly equipped for plenum ventilation were filled with a dense smudge. The room was cleared of smoke only after thirty minutes.

Dr. Fish also experimented with a square room by removing all the windows. He found that the smudge was driven back against the further wall where it remained. To remove the vitiated air best, Dr. Fish found that raising the ceiling to a peak like the ceiling in the attic of a house was most efficacious. With this system, he found that with the monitor windows open the dense smudge passed out of the room in a few seconds. The monitor system removed all odors and made the air inside seemingly as pure as out-door air.

The monitor system presents many architectural problems when a building of more than one story is concerned. However, these are not insurmountable. Another disadvantage is that a little more heat is required. Still another objection sometimes offered is that it would hardly be practical in certain noisy or dirty places in the city.

The advantages of the system are that it is easily regulated, it causes no perceptible drafts, and it keeps the air as pure as out-door air.

# Sherman's Polyvalent Vaccines

A more adequate and rapid immunity can be established with polyvalent vaccines than from an infection itself. SHERMAN'S POLYVALENT VACCINES rapidly stimulate the metabolism and defense of the body with a resultant prompt recovery in general acute infections.

Given early, bacterial vaccines almost invariably cut short the common pyogenic infections of the skin, mucosa joints and tissues;

Administered in advanced cases, they usually ameliorate or abbreviate the course of the disease;

Even when used as a last desperate expedient, they often reverse unfavorable prognosis.

The immunizing powers of stock vaccines are demonstrated by the prophylactic efficiency of typhoid vaccine. Bacterins made from selected, vigorous organisms are far higher immuno-producers than autovaccines prepared from feeble, degenerated organisms sometimes found in the patient's own specimens. Especially in acute cases, the PROMPT injection of a stock bacterin is decidedly preferable to the DELAYED injection of an autogenous one. The place for autovaccines is in chronic infections which fail to clear up under stock bacterins due to the prob-

able presence of some unusual bacterium.

Advanced inflammatory processes due to only one class of bacteria are rare, mixed infections being the rule. Therefore, COMBINED VACCINES, containing all strains likely to be present, give the best assurances of success; an unneeded variety of the bacterin is harmless and in no way weakens therapeutic response.

Thus the favorite invaders of the nose and throat are the pneumococcus, the streptococcus, the staphylococcus and the micrococcus catarrhalis, calling for Sherman's No. 40, and in chronic cases—when there is a foul odor produced by the Friedlander bacillus—Sherman's No. 36. In visceral infections, due chiefly to the colon bacillus with the pus cocci, Sherman's No. 35 is appropriate. In Neisser infections, if these organisms are not already allied with the gonococcus, the imminence of their entrance is so great that the rational combination is Sherman's No. 49.

When, particularly in grave cases, valuable time may be lost in securing the variety of vaccine especially recommended, it is always advisable to use the vaccine at hand which contains the predominant organism of the disease to be combated.

## Sherman's 10 Mil Container

This package has many superior features which assure asepsis, prevent leakage and facilitate the removal of contents. It is constructed on the well known Sherman principle.

The vial is amply strong which prevents breakage so frequent with shell vials.

We are exclusive and pioneer producers of Bacterial Vaccines. Originators of the aseptic bulk package. Pioneer in elucidation, experimentation and clinical demonstration.

## Osler on Modern Medicine

THERE is a deep fascination in the study of the history of science and in acquaintance with the lives of the pioneering spirits who have advanced its boundaries, often at such tragic personal cost. We can find, however, much more than a romantic pleasure in such study. In the words of Hippocrates, with which Sir William Osler begins "The Evolution of Modern Medicine," "we ought not to reject the ancient art, as if it were not, and had not been properly founded, because it did not attain accuracy in all things, but rather, since it is capable of reaching to the greatest exactitude by reasoning, to receive it and admire its discoveries, made from a state of great ignorance, and as having been well and properly made, and not from chance." The careful analysis of the growth of knowledge, the appraisal of each advance, and the consideration of its limitations, furnish invaluable lessons in the technique of reasoning and of experimentation so that the student who delves into the history of his field will gain not only an inspiration to renewed effort but an admirable training for the prosecution of his tasks.

Dr. Harrison describes Osler as "the best-balanced, best-equipped, most sagacious, and most lovable of all modern physicians." There has certainly been, for a generation, no representative of the medical profession better fitted to prepare a brief and popular survey of its history. Deeply-grounded in the sources, ripe in scholarship, judicious, temperate, and charitable, and withal full of the sacred fire of enthusiasm for science and for the men of science, he has conferred in this posthumous work a boon upon every student of medicine or its allied fields.

The lectures delivered eight years ago under the Silliman lectureship at Yale were in Sir William's hands for proof correction when the war interrupted all such pleasureable activities, and they have been finally prepared for the press with affectionate care by Dr. Garrison and other friends since the author's death. They constitute in his own words "an aeroplane flight over the progress of medicine through the ages," with chapters on primitive medicine, on Greek medicine, on mediaeval medicine, on the Renaissance, and the Rise of Anatomy and Physiology, on the Rise and Development of Modern Medicine,

and on The Rise of Preventive Medicine.

The specialist on the history of medicine will, of course, find little that is new in a book of somewhat over 200 pages on so vast a theme. He will, however, be delighted with flashes of insight, with exquisitely apt characterization, and with the just balance held throughout. Who but Osler could compact as much of the history of two hundred years into one sentence as the following contains: "The sixteenth and seventeenth centuries did three things in medicine—shattered authority, laid the foundation of an accurate knowledge of the structure of the human body, and demonstrated how its functions should be studied intelligently—with which advances, as illustrating this period, may be associated the names of Paracelsus, Vesalius and Harvey."

It is particularly to the student and to the younger man in medicine that this book will come as an inspiration and a delight. To catch a glimpse of the lives and the work of Hippocrates and Galen and Avicenna, of the three pioneers of the Renaissance whose names have just been mentioned, of Morgagni and Hunter, and Laennec, of Pasteur, Koch and Lister, of Reed and Gorgas, pictured

with Osler's clarity and charm is to enter as a younger brother into the great company of the torchbearers of science and to gain new power for the task of carrying onward the light they kindled.—C.-E. A. Winslow.

Yale University Press, 1921.

### The Principles of Therapeutics

This book, by Oliver T. Osborne, will do much to fill the need for a clear, rational and efficient textbook of treatment which the young practitioner so earnestly needs. The contents, classification and arrangement are excellent. Especially praiseworthy are the discussions of electrotherapy and hydrotherapy, instructions as to the technic of inhalations, irrigations, etc. The discussion of topics, such as medical laws and ethics, is likewise unusually valuable. The book maintaining the decimal system of dosage throughout will unquestionably help to educate after at first confusing the under-graduates, still being trained in the grain and ounce system.

To the reviewer a jarring note in the unusually even tenor of the book is found in the author's too frequent use of words such as "nonsensical," "inexcusable," "absurd," "ridiculous," in discussing the opinions of others. This is, perhaps, a minor criticism in a major volume.

W. B. Saunders Company, 1921.

### Mouth Is Gateway to Health

N. Y. County Red Cross.

Prevention on a large scale is practiced by the New York County Chapter, American Red Cross, in its program for cleaning the teeth of New York school children. The chapter maintains four dental clinics in public schools and three others in Red Cross Child Health Stations. Children in Public School No. 168, Manhattan, are shown here receiving their daily teeth cleaning. The School of Oral Hygiene of Columbia University cooperates with the Red Cross Health Service in this work.

# Science approves food conservation

**S**CIENTISTS and economists can no longer fail to take account of the important place vegetable fats have assumed in our national dietary. Production of animal fats has not kept pace with the demands of a growing population, and vegetable fats have been drawn upon for certain limited uses to supply the deficiency.

Vegetable fats have established a place from which they cannot be displaced without serious disturbance to the food supply. Vegetable fats are here to stay and the problem for the scientist now is to study their uses.

Combined with skimmed milk, vegetable fat is made to serve the highly economical purpose of saving a food product which is otherwise lost to the human dietary. Thus enriched, skimmed milk is an excellent cooking liquid, adding nutritive value to foods cooked with it and helping to balance the diet.

How HEBE is helping to save a part of the enormous quantities of skimmed milk produced by the butter industry is told in "Today's Food Problem," a booklet published especially for physicians, health officials, dietitians, public health and industrial nurses.

HEBE is produced in modern thoroughly sanitary condenseries, hermetically sealed and sterilized in the can. It is pure skimmed milk evaporated to double strength enriched with vegetable fat, labeled, advertised and sold frankly for just what it is.

This booklet and also another booklet,

"HEBE. Its Dietetic and Economic Value," will be sent free together with a can of HEBE for examination and trial. Address 2422 Consumers Bldg., Chicago.

THE HEBE COMPANY

Chicago

Seattle

## American Apprenticeship and Industrial Education

The decay of the apprenticeship system and the development of industrial education on broader lines has come in large part in the failure of the workshops to provide a proper industrial training for its younger employees. Paul H. Douglas in a study of "American Apprenticeship and Industrial Education" traces the use and decay of the apprenticeship system, the problem of juvenile labor and the educational requirements of modern industry, the modern substitutes for apprenticeship such as manual training, trade and industrial schools, and the general social and economic aspects of the schools.

Apprenticeship is in reality a combination of education and industry. The apprentice is taught the trade by one engaged at the time in the industry and when this process ceases the system becomes merely routine. Since the shop no longer trains its workers, other agencies must be created and utilized to assume the responsibility.

Columbia University, Longmans, Green & Co., Agents, New York, 1921.

## Physics and Fiction

A remarkably instructive and entertaining book, "*Physic and Fiction*," written by Sir Squire Sprigge, the editor of the *Lancet*, has been published recently. The book deals with several phases of medicine and is, in fact, a collection of essays on doctors and the relationship of the medical profession to the art of fiction, etc. The first chapter, "Medical Priestcraft," points out that, although the profession is not now regarded with the reverence it once commanded, there never was a time when it demonstrated its efficiency so forcibly than at the present time.

Perhaps the most amusing chapter is that which is concerned with "Medicine in Fiction." Of course the author finds many misrepresentations of medical life in modern novels and the manner in which diseases are described is nearly always faulty and sometimes absolutely fake. He draws attention, for example, to the fact that the devoted nurse who saves and afterwards marries the hero is impossible in real life. "Nurses in hospitals have to do as they are told," he writes. "The devoted young woman who remains by a sufferer's pillow hour after hour and day after day till she wins a hand-to-hand fight with fate, and secures by her importunity

the life of the patient, is a figment; for in the hospitals all nurses go to their meals and their beds at stated times."

Occasionally the novelist, however, is not only accurate in his description of diseases but has even anticipated the doctor. In Charles Reade's "Foul Play," one of the characters, a young woman, is dying from phthisis. Circumstances left her on a desert island where she has to sleep in a hastily constructed log-shelter and labor all day beneath the sky in accordance with the habits of brave castaways. She puts on weight, increases in strength, and utterly loses her tuberculous infection. This book was written in 1868 and at that time few save George Bodington, the first to advocate the open-air treatment of tuberculosis, would have believed the episode possible. Bodington's book was written in 1840 but the teachings were coldly received and by 1868 were forgotten.

The chapter dealing with public developments of medicine is particularly good and surveys the progress of preventive medicine and the work of the Ministry of Health in the way

that they should be regarded. It is pointed out that general practice in Great Britain as hitherto understood is largely in the melting pot. It is further pointed out that if the public will cooperate with the medical profession—and it must be educated to do this—the future of preventive medicine and of medical practitioners is bright.

The book is written in a manner entertaining and instructive. The author's views, though somewhat detached, are never dogmatic, they abound in discernment and foresight; they are tolerant and philosophical, expressed in language well chosen and of a high literary style. The work should appeal to American medical readers who desire to know how the profession stands in Great Britain. Moreover, while it provides a fund of information, it is never dull.

Hodder & Stoughton, London, 1922.

Even though the "nuisance taxes" yield the Government \$50,000,000 a year, there is general agreement that the return does not justify the injury done the good nature of the American people.

## Economy in Mass Treatment

BY OUR LONDON CORRESPONDENT

The advantages of the large tuberculosis sanatoriums as weighed against those of the small hospitals were discussed in a paper read by Dr. E. Lindhagen at the second meeting of the Scandinavian Tuberculosis Society at Numela Sanatorium in Finland, report of which is published in *Hygiea*.

From his broad experience, Dr. Lindhagen believes that big institutions, well built and well staffed, are economically of more value and afford the patient more expert treatment. Dr. Lindhagen in his paper pictures the fate of patients tucked away in small twenty-five bed hospitals under the supervision of a non-resident general practitioner without any special knowledge of the modern treatment of tuberculosis. The physician must often be away for days at a time and when an epidemic is raging in the district, the last patients to be attended to would probably be the inmates of such a small hospital.

As compared with such a hypothetical case, Dr. Lindhagen believes a large institution with a staff of specialists to be far more satisfactory. The treatment of pulmonary

tuberculosis of late years has become a highly specialized, frequently operative science; even the older methods of dieting, graduated exercise, and the like require skill and experience on the part of the medical staff.

Dr. Lindhagen does not believe in frittering away money on small cheap shanties as is often the case nowadays. He believes that in the near future the policy of makeshift, ramshackle, jerry-building will be condemned as expensively cheap; small and isolated hospitals will have to be scrapped; and the capital expended on them written off wholesale. It would be far better, he says, to build large permanent, up-to-date institutions.

Dr. Lindhagen has made out a good case for the large as compared with the small institution but the latter's vigorous growth in Norway suggests that more can be said on its behalf than is conceded in his paper. In fact the tendency of the present day is to build somewhat flimsy buildings, having plenty of fresh air in which to house consumptives rather than to spend a great deal of money on solid buildings.

# KOTEX

## One Problem Less

**S**TUDY lamps instead of pine torches. Printed books instead of written parchments. Women welcome instead of barred at schools of higher learning.

Habits and customs change. Living conditions improve. Grandmothers and mothers used birdseye and other bulky sanitary pads. Today a new sanitary habit has been made possible by Kotex.

Kotex is a sanitary pad that does away with many embarrassments. It is easy to buy without saying "sanitary pads" by simply asking for "Kotex." It is sold in department, drygoods and drug stores. Everywhere. It comes in a blue box

which has no printing except the name "Kotex."

Kotex solves an age-old laundry problem by removing it, for Kotex is cheap enough to throw away and easy to dispose of by following simple directions found in each box. Two sizes—Regular and Hospital size (extra large). Many find it economical to have a supply of each. No comparison between Kotex and old fashioned birdseye.

The first box usually—the second box always—results in the discovery of a new comfort, a new convenience, a new economy, a new habit. Keep Kotex always on hand. Ask by name for Kotex.

*Regular Size  
12 in box*

*Hospital Size  
6 in box*

*Sample of either size mailed in plain wrapper for 10c.*

*Kotex cabinets are now being distributed in women's restrooms every where — hotels, office buildings, theatres, and other places from which many women bring home Kotex with the safety pins in plain wrapper for 10 cents.*

## FROM THE FIELD

The National Research Council has published in its Bulletin of December 1921 a list with relevant information of the research laboratories in industrial establishments of the United States. This was originally compiled by Alfred D. Flynn but has been revised and enlarged by Ruth Cobb of the Information Service. In addition to the alphabetical list of laboratories which carries first hand information of the work, there is a subject classification.

The advantages of a doctor's information exchange as operative in Lafayette, Ind., are set forth in the *Ohio State Medical Journal*. The exchange is available to all physicians in the city and affords a permanent telephone service.

The Massachusetts Compulsory Education law requires "that every child between seven and fourteen, every child under sixteen who does not meet the requirements for the completion of the sixth grade of the public schools of the town in which he resides . . . shall attend a public day school . . . or some other day school approved by the committee, during the entire time the schools are in session."

The Eyesight Conservation Council has issued "Eye Sight Conservation" Bulletin No. 1 which comprises that part of the study of "Waste in Industry," conducted under the auspices of the Federated American Engineering Societies which relates to eye conservation. The importance of the subject, corrective measures for substandard vision, and the health factors involved are fully discussed in the pamphlet.

A psychiatric clinic to be attached to the Juvenile Court at St. Louis is being advocated by a number of St. Louis physicians and social workers. Dr. M. A. Bliss of St. Louis, president of the Missouri Society of Mental Hygiene, has announced that the National Society of Mental Hygiene will cooperate in its establishment. The Rockefeller Foundation will provide funds to send a psychiatrist, a psychologist, and social workers should the clinic be established.

Stanley Cobb, M.D., Assistant Professor of Neuropathology, Harvard Medical School, has published in *The Journal of Industrial Hygiene* "A Report on the Brief Neuropsychiatric Examination of 1,141 Students." This examination is given to each man entering the Freshman class at Harvard University.

A clinic designed to bring children who are forced to earn their own living up to a higher standard of health and physical development has been established by a group of woman members of the First Unitarian Church, Baltimore. Dr. Lawson Wilkins of the Johns Hopkins Hospital held the preliminary clinic at the parish house. The clinic will be held every Friday morning. This is the first move of the kind in the state, and is being encouraged by members of the State Board of Labor and Statistics to which children must apply for permits to work.

Plans have been filed for the new home of the Hospital for Joint Diseases which is to occupy the block front on the east side of Madison between 123d and 124th streets, New York City. There will be two buildings, a seven story hospital, the estimated cost of which is \$650,000, and a six story service building costing \$250,000.

Michigan has organized a public health education committee composed of M. L. Burton, Ph.D., President of the University of Michigan, president, and Dr. Frederick C. Warnshuis, Grand Rapids, secretary. The object is to carry out with the cooperation of the Michigan State Medical Society and the University a general health program for the state. Membership on the committee includes: Dr. Andrew P. Biddle, president of the Detroit Board of Education; Dr. William J. Kay, Lapeer, president of the Michigan State Medical Society; Dr. William J. Dubois, Grand Rapids; Dr. John McLurg, Bay City, and all members of the State Medical Society. The university committee is composed of Dr. Hugh Cabot, dean of the Medical School, University of Michigan; Dr. Gotthelf Carl Hubert; Dr. John Sundwall, and Prof. W. D. Henderson.

Persons suffering from venereal diseases are prohibited by Federal law from migrating from their home state to another without first procuring from their local health officer a permit stating that their travel is not dangerous to public health. The law seeks to close every channel through which venereal disease may be spread. As a result of the request of the United States Public Health Service last spring the Attorney General instructed all United States attorneys to prosecute offenders rigorously. This resulted in the sentence of several violators to reformatories, thus stopping their disease-spreading activities.

With the discovery of "205 Bayer," a new drug made in Germany, great hopes are being held for the cure of the sleeping sickness caused by the tsetse fly in the Congo region, states Dr. E. R. Kellersberger in the *New York Times*. Dr. Kellersberger has been a member of the Luebo colony for five years.

George Dock, M.D., of St. Louis tells of a visit to the Palmer School of Chiropractics, Davenport, Iowa, in the *Journal of the American Medical Association*. The visit revealed no laboratories to speak of and a student body composed mainly of middlewesterners from the farm, barber shop, and hotel dining room. The article is reprinted in the *Journal of the Missouri State Medical Association*.

The Montclair Board of Health has extended the work of its laboratory to include the Wassermann reaction. This work will be under the direction of Helen G. Jacobs, B. S., who has recently been studying the technique of the test at the research laboratories of the New York City Health Department under the direction of Dr. William H. Park and Miss M. A. Wilson.

In an effort to provide adequate medical service for the middle class, some of the leading physicians in Kansas City have established a hospital inviting the public to become members of the association by paying a dollar a month each and receiving therefor such medical or surgical care as may be needed.

Japan's plan of inoculating dogs instead of people to prevent rabies might well be considered in America. Of 31,000 dogs inoculated not one case of rabies developed.

## Thermolite Design Was Correct

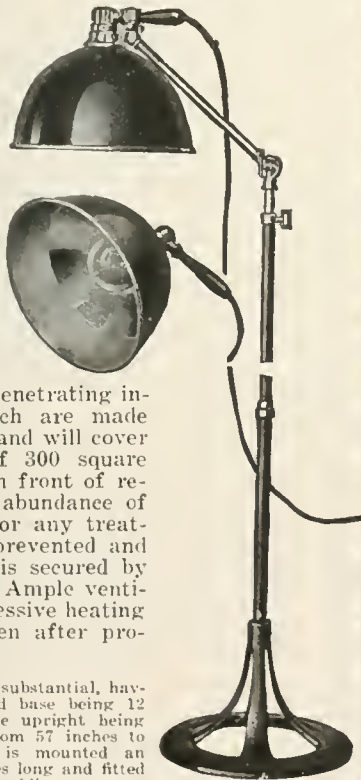

It is interesting to note that leading phototherapists now endorse the use of therapeutic lamps reflecting PARALLEL RAYS and without a focal or "burning" point.

The greater therapeutic value of parallel rays has always been recognized in the design and construction of Thermolite heat and light applicators and this fact has undoubtedly influenced the adoption of this equipment as standard in many institutions.

## The New THERMOLITE

LIGHT AND HEAT APPLICATOR is particularly adapted for institution use, easily portable and readily adjustable to any position. Yet the outfit on account of the especially constructed reflector and special lamp delivers a powerful parallel beam of radiant light and heat. The outside aluminum reflector has a diameter of 12 inches with a highly polished parabolic aluminum mirror inside. A special 375 watt, 120 volt, 100 candle power lamp is used. Remarkable therapeutic action is derived from the penetrating infra red rays which are made slightly divergent and will cover a circular area of 300 square inches, 36 inches in front of reflector. While an abundance of heat is provided for any treatment, burning is prevented and great penetration is secured by the parallel rays. Ample ventilation prevents excessive heating of metal parts even after prolonged application.

The floor stand is very substantial, having a heavily weighted base being 12 inches in diameter, the upright being adjustable in height from 57 inches to 96 inches, on which is mounted an adjustable arm 12 inches long and fitted with a ball clamp providing a great range of adjustments.

*May we send you full particulars regarding this hospital outfit?*

## 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

A useful factory inspection form is contained in the January 6 issue of *Public Health Reports* issued by the United States Public Health Service. The January 20 issue contains a study by Fritz B. Talbott, M.D., Boston, assisted by Miss Margaret E. Moriarty on "The Basal Metabolism of Infants Fed on Dry Milk Powder."

Dr. J. H. Florence has been appointed State Health Officer for Texas to succeed Dr. Manton M. Carrick, resigned. Dr. Florence is a native Texan and was educated at Baylor University. Dr. W. H. Beazley, Assistant State Health Officer, is also a native of Texas. He was educated at Louisville, Ky.

Health and nutrition certificates are awarded those Texas children of pre-school age who for four consecutive years have been given physical examinations by local physicians and dentists, according to the *Houston Chronicle*. The certificates are signed by the local health chairman and by a representative of the home economics division of the University of Texas. During the four years health records are kept for each child and the public health nurse of the community keeps in touch with the parents in an effort to correct any defects disclosed by the examinations. Examinations are now being held for the third year in about 25 towns.

Health service for negro women in industry is discussed in a report recently issued by the Woman's Bureau of the U. S. Department of Labor. Miss Emma L. Shields, a member of the staff of the Women's Bureau, in conjunction with the Division of Negro Economics in the Department of Labor, carried on the investigation.

Provisions for health service in the establishments visited varied from the best to the worst types. In 18 establishments, employing 2,502 negro women, adequate and sanitary first aid dispensaries were found under the supervision of trained nurses. Employers were unanimous in emphasizing the good results emanating from these arrangements. Not only could expert aid, quiet, and comfort be given the worker who had been taken ill or who had met with accident in the factory, but in many cases the influence and the advice of the nurse had an effect on the daily habits of the workers, both in the factory and in their homes, and was being reflected in better living. It may be remarked in passing that sympathy and understanding seemed to exist between negro nurses and the workers of their own race, giving these trained women

a strong influence for good on the factory workers.

In 132 establishments either there was no equipment for the treatment of illness and injuries, or there was a nominal first-aid cabinet containing one or two medicines to be administered indiscriminately as the panacea for any ill. Some managers seemed surprised when equipment for health service was mentioned. In many cases they replied that they had a standing agreement with a hospital for treatment of their accidents and for ambulance service at top speed. In many establishments managers had no health or accident records by which they might keep account of health conditions in their plants and ultimately reduce losses in labor caused by preventable illness or accident. The 18 establishments with proper health equipment showed that they realized the significance of this phase of factory management by keeping records of all sickness and accident cases.

Alcoholism and home-brewism was responsible for approximately one-third as many victims in Michigan in 1921 as was "good licker" in 1917, states the Michigan Department of Health. In 1917 a total of 255 deaths was credited to alcoholism; in 1921 there were 94.

The Committee of Fresh Air and Recreation of the Babies' Welfare Federation is attempting to draw up a set of uniform essential minimum requirements for admission. This is for the purpose of minimizing the danger of contagion and vermin to the children who are transported each summer from the tenements to the country by the various fresh air organizations. Cleanliness of body, head, and clothing are the standards the committee hopes to have adopted.

The Medical Society of the County of New York has issued a statement accusing chiropractors of flooding the country with propaganda to discredit all other means of treating diseases and to break down all health laws with which they come into conflict. Chiropractic pamphlets are distributed by a central bureau by the hundred thousands. The claims of its testimonials have been investigated by the *Journal* of the American Medical Association and found to be untrue, the Society further states.

More than 20,000 persons committed suicide in the United States in 1921 according to an estimate of the Save-A-Life League appearing in the *New York Times*.

The Surgeon-General has ordered modification of fumigation requirements for ships in the port of New Orleans. Ships which dock at rat-proof wharves must be fumigated only once every six months instead of three as heretofore. Ships that dock at the few wharves that are not rat-proofed must follow the old regulations.

A bill providing for the serving of breakfasts and luncheons at cost in the 600 elementary and high schools of the five boroughs of New York City was presented in the state legislature, February 15. Under the present system, the Board of Education is supplying luncheons at a maximum price of 10 cents in twenty-four of the schools where the percentage of malnutrition is highest.

Up to March 10, thirty-four states had signified their acceptance of the provisions of the Sheppard-Towner Act. In six states the acceptance was by act of the legislature and in the rest through the action of the governor, this being authorized by the law for a period extending until six months after the adjournment of the first regular session of the legislature following the passage of the act. In twenty-nine states the administration of the act will be in the Child Hygiene or Child Welfare Division of the State Agency of Health; in two States, New Mexico and Nebraska, in the State Department of Public Welfare, which includes the State Agency of Health; in Delaware, the Child Welfare Commission will administer it, and in Iowa and Colorado, the Department of Education. The plans now being developed by the states will provide for general educational activities through popular literature, reports of investigations, and surveys, with the ultimate aim of making actual conditions known and thus providing the basis for their correction.

Acute infectious jaundice is now epidemic in the United States for the twentieth time in seventy-two years, according to reports in the *New York Times*. The disease has appeared in practically every section of New York state and sixty-nine cases were reported at Yale University. The germ, the *Leptospiraicterhaemorrhagia*, is carried by rodents. Rat extermination and protection of food from rat contamination is advised by health authorities.

# LOESER'S INTRAVENOUS SOLUTIONS

## Every Physician Should Read THE JOURNAL OF INTRAVENOUS THERAPY

A sixty-four page Journal, containing original articles, reprints and abstracts relative to Intravenous Medication from foreign and domestic medical journals.

The most comprehensive compilation on the subject, including laboratory and clinical reports.

Copy mailed on request.

### NEW YORK INTRAVENOUS LABORATORY

100 West 21st Street

NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions  
for the Medical Profession Exclusively.*

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

Address .....

City..... State .....

The validity of the rules of the state department of public health for the control of typhoid carriers was upheld by the Supreme Court of Illinois in its recent decision in the case of *Barmore v. Dr. John Dill Robertson*, former Commissioner of Health of Chicago. The court held that the constitutional guarantee that no person shall be deprived of his liberty without due process of law was not intended to limit the exercise of the police power of the state such as the enforcement of quarantine regulations.

Lewis H. Carris, of Washington, D. C., has accepted the invitation of the National Committee for the Prevention of Blindness to become its field secretary. Until January 15, Mr. Carris was administrative head for the Federal Board for Vocational Education in charge of the administration of the Federal Vocational Educational Act and the Industrial (civilian) Rehabilitation Act.

The American Medical Association will hold its annual session at St. Louis, May 22 to 26. Dr. Louis H. Behrens, 3525 Pine Street, St. Louis, Mo., is chairman of the Committee on hotels.

The annual congress of the Royal Sanitary Institute will be held at Bournemouth, England, July 24 to 29 under the presidency of Major John Seely.

The new anti-tuberculosis act which makes state support available to private organizations instead of attempting to increase the number and scope of public institutions is considered by *The Survey* to be one of the most important of recent public health laws in Belgium. A new national association of private organizations to combat tuberculosis which has been formed will receive a state grant of several million francs.

A bill which has excited numerous protests has been presented in the French parliament providing for the extension of the health insurance operative in Alsace and Lorraine to the rest of the country. Compulsory and old age insurance was organized in Alsace-Lorraine when the province was part of the German Empire. Now that it has become part of its mother country again, it still maintains its well organized social insurance laws.

An International Congress for the protection of mothers and infants will be held in Paris, July 6 to 8, 1922. The conference is being called by the League to Combat Infant Mortality.

Senator Frederick M. Davenport of Oneida has introduced into the New York legislature a bill providing for the establishment in the state department of health a division of maternity, infancy, and child hygiene. The proposed bill carries an appropriation of \$100,000. Legislative leaders have decided not to accept federal aid in maternity care as provided by the Shepherd-Towner Act as they consider it undue interference in state affairs by the federal government.

Chicago must have clean streets is the ultimatum of William Burkhardt, Deputy Commissioner of Public Works, recorded in the *Chicago Tribune*. Since the city council appropriated an additional \$500,000 for waste disposal a month ago the number of loads of refuse hauled daily has jumped from an average of 1,000 to 3,700.

A Hospital Information Bureau has been established in the New York Academy of Medicine Annex, New York City, with Dr. E. H. Lewinski-Corwin, Executive Secretary of the Public Health Committee of the Academy of Medicine, as director. The purpose of the Bureau is to keep in touch with hospital work and progress in New York City, to prepare exhibits, maintain a library of hospital reports, and to promote uniformity in hospital reporting.

A number of physicians from the London School of Tropical Medicine will attend courses at the proposed Gorgas Memorial Institute of Tropical and Preventive Medicine at Panama, according to announcement made by Sir Patrick Manson, advisory member of the institute. Dr. Richard P. Strong, dean of the school of tropical medicine, Harvard University, who has accepted the post of scientific director, sailed April 1 for Panama to assume his new duties.

The Lying-in Hospital of New York City celebrated the 123d anniversary of its incorporation March 1. According to estimates the hospital has brought into the world over 131,000 babies, or enough to populate a city larger than Springfield, Mass.

Dr. A. D. Emmett of Detroit, Mich., presented a paper recently on "Some Newer Phases of Vitamin Studies," before the Chicago Medical Society. The medical profession should give more attention in the future to diet and nutritional factors in the treatment of patients. They should bear in mind that vitamins are only one factor to be considered and that proteins, mineral matter, calcium and phosphorus, as well as energy producing values should all be in the right proportion, Dr. Emmett stated.

*The Red Cross Courier* is presenting a series of articles by Anna M. Stanley on the technique of school nursing. Miss Stanley was formerly director of public health nursing of the Southwestern Division of the Red Cross, and has had much first hand experience as school nurse, supervisor of school nurses, and as a teacher.

The New York post office has established a dispensary for its employees on the fourth floor of the central office which will be in operation day and night. It will care for the 3,000 men and women employed there and also for those in the branch offices. Col. E. K. Sprague, head of the Hudson Street Hospital, will be in charge. The United States Public Health Service is supplying the equipment and will maintain the clinic.

The annual meeting of the Canadian Public Health Association will be held June 6 to 9 in St. John, New Brunswick. The annual meeting of the Canadian Association for the Prevention of Tuberculosis will be held in connection with the Canadian Public Health Association. The Canadian National Council for Combating Venereal Disease will also hold its annual meeting in St. John.

The New York State Commission to Examine Laws Relating to Child Welfare has opened offices with an Executive Secretary in charge at 137 East 22d Street, New York City. George A. Hall is executive secretary.

The address of Edwin O. Jordan, Professor of Hygiene and Bacteriology, University of Chicago, delivered before the second general session of the American Public Health Association in New York City on "The Relations of Bacteriology to the Public Health Movement since 1872" is published in *Medical Insurance and Health Conservation*.

## The American Dollar and "AMERICAN" Sterilizers

An advertisement worth the reading of any interested in the purchase of sterilizing equipment—and directed particularly to those seeking the most for their expenditure.

**W**ITH all eyes centered upon Price, the purchasing power of the American dollar has never been so taxed as it is today.

We sense that you are not immune to the price appeal in the purchase of your equipment. You are seeking the very most your money will buy—and rightly so. It is, therefore, a source of keen satisfaction to us to know and be able to prove that

at present prices represent the greatest Sterilizer and Disinfecter value obtainable. Notwithstanding the fact that they cost more to manufacture, due to the use of finer materials, more searching tests, more scientific and precise shop and machine work, more exacting inspection, and are consequently worth far more to the owner, they are sold today for less per unit of value than any similar apparatus made. Greater skill, greater specialization, greater achievement do not make the "AMERICAN" cost more—they do make it worth more.

And the purchase price, low as it is, is greatly lessened in the after years of uninterrupted service because of low maintenance and operating costs. Your dollar has been creditably spent when it goes for "AMERICAN" apparatus.

Descriptive bulletins, engineering data and specialists' counsel are free for the asking.

**STARTRIGHT**  
WALKING SHOE

The  
"Startright"  
Oxford

**W**E are taking this opportunity to present to the readers of The Nation's Health, the Startright Walking Shoe which is the best made orthopedic shoe on the market today. The Startright shoe really is an Orthopedic Shoe in Disguise, because it combines style and comfort and most women select Startrights for their appearance alone, forgetting the orthopedic qualities. Nothing but the highest grade materials and workmanship ever used in Baker shoes.

Startright shoes have been "approved" and are straight on the inside, have a flexible arch, plenty of swing to the toe to allow the proper movement and a low flat heel.

The Startright is our most popular model and is made over our 505 pattern.

Ask your dealer for Startrights and if he doesn't stock them—write us direct. Carried in stock in eleven styles.

## Immigrant Health and the Community

The problem of the immigrant as a cog in the political world and as a factor in social reorganization has received much attention but his health problems and difficulties have not been perhaps so greatly emphasized. Michael M. Davis, Jr., through the courtesy of the Carnegie Corporation of New York, has just published a study in the Americanization series entitled "Immigrant Health and the Community." The book is divided into five parts giving statistical and special problems, a discussion of American agencies and methods, and a program for health.

In some communities the immigrants have developed organizations for self help which are entirely independent of any American agency. Many of the Southeastern Europeans bring over with them ideas of cooperative associations which they continue in this country and although it may originally be started as a social, cultural, or political group, some scheme of sickness or death insurance is ordinarily included.

The problem of maternity care, the midwife and her extensive activities are discussed at some length. In the

United States our knowledge of midwifery is limited, but from communities in which their work is regulated and supervised it would seem evident that at least they give as good care as any other which the mass of people can pay for on a business basis. Immigrant diets and American food also afford special immigrant problems.

The program for health is limited by economics, psychological, professional, and social factors. The average immigrant has insufficient income to meet the emergency of sickness and is limited not only by his own foolish ideas of sickness and its causes but an entire lack of understanding of the problem of the physician. Professionally, specialization and skill is required of physicians. To these there is success generally through hospitals and dispensaries. Socially some system must be worked out to give adequate service to all people of small means and little health knowledge, whether in the form of health insurance, the community organization of medical services, the development of health centers and service organizations, it is impossible to say. There are tasks for national and local organizations, standardizing and developing plans, stimulating various groups, and pushing the general

standards on to a point more nearly commensurate with our national ideals.

Harper & Bros., New York, 1922.

## Infantile Paralysis Treatment

There is probably no other man in this country who knows as much about treatment of infantile paralysis as does Professor Lovett. His book on "Treatment of Infantile Paralysis," may therefore be considered as the latest word on the subject.

The author believes in complete rest in the acute stage of the disease. He is opposed to all forms of massage and electrical treatment, up to the time all muscle pain has disappeared. He uses casts for the prevention of the deformity. After the acute stage is over, he advises muscle training.

Although some few men in the country differ from Dr. Lovett as to procedure, it is best for the general practitioner to follow his advice and method. A thorough reading of this book must be considered as essential to every one who comes in contact with patients suffering from infantile paralysis.

P. Blakiston's Son & Co., 1921.

## Doctors Need Protection

Just as much as business men. In some ways they need it more.

A Doctor's business cannot very well be carried on by his family; yet it means the same to them as the business of a merchant or banker.

The Doctor's stock in trade depends upon his professional training, skill and ability.

Every professional man is in duty bound to give some consideration to the conditions which affect his business, his family and his old age.

## MEDICAL AND HEALTH RECORD FORMS

THERE is both a moral and a professional responsibility on all agencies engaged in organized medical and health service to maintain permanent records in such form that the results can be compared with the statistics of all other agencies in the same field.

*This calls for standardization of record forms.*

Because of unexcelled facilities for production, and because of our experience in the development in conjunction with the American College of Surgeons of standardized hospital record forms, the Faithorn Company is able to offer you a broad service in the development and the manufacture of medical and health record forms for all purposes.

If your present forms do not fully meet all requirements we shall be pleased to co-operate with you in solving your problems.

## Good Bed Most Important Piece of Furniture

A good, comfortable bed is by far the most important piece of furniture in the house says *The Forecast*. for no one can get along without a bed. Upon its comfortableness and cleanliness the efficiency and health of the sleeper depends.

A good mattress and good springs are indispensable to a good bed. Sheets, pillows and mattress should all be clean. A light-weight, quilted pad over the mattress which can be easily washed adds to the comfort of the bed. Sheets should be from 24 to 36 inches wider and longer than the mattress allowing plenty of room to tuck in the ends and sides and to turn down the wide hem end to keep the blankets clean.

Blankets should be soft and fluffy and contain a large proportion of wool as these are considered more comfortable and durable if given proper care than cotton. Wool or cotton bathing comforts covered with cheesecloth and then with a pretty light weight material are very convenient for extra covering in severe weather and are warmer than the old fashioned quilts.

## Smallpox Peddler Spreads Disease in Kansas

That vaccination is the greatest safeguard against the operations of the ignorant and criminally careless is pointed out by Dr. Frank G. Pedley, State Epidemiologist, in the *Bulletin of the Kansas State Board of Health*, in citing the case of a man who by ignoring his quarantine caused the spread of smallpox to three counties involving fourteen persons and resulting in four deaths.

The "smallpox peddler" first acted as nurse to a fellow member of a road gang who had become ill from black smallpox in Garnett, Ander-

son County, about October 15, 1921. Not caring for the solitude and isolation of the job, W— often went to town. Upon being warned that he was breaking the law and fearing arrest, he boarded a train one night and disappeared.

Two weeks later W— appeared in Iola, Allen County, and reported sick. His illness proved to be smallpox, he was isolated, and after ten days of fairly severe illness, feeling as well as ever, he decided to leave Iola and be married.

The wedding trip included a visit to Thayer, Neosho county, where he visited three families. This was about November 18. The first week of December smallpox broke out in the three families and the fourteen cases resulting can be traced directly to W—. His wife and mother-in-law also contracted the disease. All this time W— did not seem to realize his liability for their illness. He left the house where they were confined and mingled with well persons daily. As soon as it was discovered that the cases in the three counties could be traced to this one man, he was placed under arrest.

From W's— ignorance and criminal carelessness at least fourteen cases of smallpox and four deaths, one of them his own mother, occurred. Many of the cases were terribly disfigured by the disease.

## Leper Segregation Not the Best Method

That segregation of lepers in the Culion Leper Colony in the Philippine Islands has not proved wholly successful is the statement of Prof. José Albert in the *Journal of the Philippine Islands Medical Association* reviewed in the *Lancet*. The Culion Leper Colony was established fifteen years ago on a specially selected island possessing every modern con-

venience. Rosenau in the second and third editions of his "Preventive Medicine and Hygiene" stated that systematic segregation has reduced by 90 per cent the new admissions to this colony, and more recently Leonard Rogers has described it as a "huge success." Albert states that these statements are not in accord with facts.

Segregation alone, Albert maintains cannot stamp out leprosy. Improved hygienic and sanitary conditions which prevent contagion are more effective. Segregation is not based on the present knowledge of the contagiousness of leprosy, the writer declares. Intimate and prolonged association produces infection in a second individual in only about 5 per cent of the cases. Rational legislation should provide for the detection and isolation of lepers with open lesions and their segregation in appropriate hospitals.

Norway's system of no segregation is cited with approval by Albert. Lepers without ulceration are permitted to mingle with others. Physicians state that they have never seen infection by contagion from cases of this nature. The success of this method of control is seen, Albert points out, in the fact that in descendants of lepers who have emigrated from Norway to the United States, the disease has disappeared. Where rigid isolation is enforced, the cooperation of the people tends to be lost as in Hawaii and more recently in the Philippines.

The "Care of the Baby," a new and enlarged edition of a former publication of the same name, is contained in the recent number of the weekly Public Health Reports of the U. S. Public Health Service and is now being reprinted for general distribution.

## Health and Atmospheric Environment

The relation of the individual to active outdoor life has been confirmed by many and varied experiments. The Japanese have developed an artistic excellence in craftsmanship in slightly built dwellings, depending not on the cold comfort of charcoal braziers, but on clothing and exercise to keep themselves warm. On the other hand in the last century, the Europeans and Americans who have dwelt in a colder climate, have bent their efforts toward the building of draftless houses, secured by artificial heating both in summer and winter. The low cooling power of stagnant air, rooms of artificial heating by radiators depresses the metabolism to a low level. In place of the body being kept warm naturally by the stimulation of cool air exciting muscular exercise and glandular activity and so enhancing the combustion of food, it is kept warm by the blanketing effect of warm stagnant air, so that sedentary occupations, amusement, and rest can be carried on in warm comfort and a minimum of open-air muscular exercise be taken, according to the *International Journal of Public Health*, May-June, 1921.

The body was fashioned for procuring food by active exercise and upon this exercise depends the proper and vigorous function of the digestive, respiratory, and vascular organs. Consequent on this, too, is the vigor of the nervous system and the keen enjoyment of life.

The authors point out the importance of deep breathing excited by exercise. Exposure of the skin to the sun and wind has a very profound effect upon the health of the entire body. There is reason to think, perhaps, that the skin is a great seat of production of immunizing substances which protect it against infection. The monotonous life of over-warm, stagnant rooms is contrary to the changing conditions of the outdoors. There must be the constant re-adjustment of the individual to his environment. Exposure to cold winds may double the metabolism of a man sit-

ting at rest. His natural inclination is not to sit still and feel chilled, but to be active and keep himself warm. It is this impulsion to activity and the raising of metabolism that makes open-air life so beneficial.

As a rule the body weight of well-nourished people can safely be reduced, but the experience of Germany during the war, and still more of Austria since that time, has "upheld the truism that in the absence of a proper food supply, all that has been written above about open air stimulating metabolism and efficiency is of no account. Cold is an enemy of the semi-starved; it is a stimulating friend of the well fed."

## Chemical Analysis of Milk

The chemical composition of milk varies greatly, not only as to fat content, but also as to protein and carbohydrate. Such variations are due to several conditions such as time of milking, period of lactation, state of nutrition, and nature of nutrition of the animal. In rating the products of given dairies, the *Lancet* suggests that consideration be given to limits of variation of all constituents, with due care that the food of the herds provides a source of all three vitamins. Summer milk is a better antiscorbutic than winter milk. The same holds for the fat-soluble A vitamin.

All three of the vitamins are derived from the food of the animal and are not produced by the animal. Further, there is no connection between chemical composition of milk and vitamin content. A milk of high fat content may be low in content of factor A. Milk from a cow on dry food does not contain C factor.

## Tuberculosis Among Indians

Results of a study of the cause and extent of tuberculosis among the Nebraska Winnebago by Doctor Margaret W. Koenig appear in a report issued by the Nebraska Historical Society. This investigation was conducted with the cooperation of the Nebraska Tuberculosis Association and Department of Sociology of the

University of Nebraska, and the field work was financed by a special grant from the National Tuberculosis Association.

More than one thousand Winnebago are included in the study. The average annual birth rate for the past decade had been 34.4 per one thousand, while the mortality for the same period was 36.2 per one thousand.

Personal examination was made of over half the population and information was obtained concerning 237 cases of tuberculosis within the decade 1909 to 1919. Of this number 127 were deceased at the time of the study, representing an average annual mortality of 11.7 per one thousand as compared with the U. S. registration area rate of 1.4 per one thousand. The tuberculosis morbidity rate among the Winnebago is from three to six times as large during the age periods of five to twenty years, as compared with the population at large. Glandular tuberculosis comprised 15.6 per cent of the cases, but as practically no milk is used by the Winnebago the infection is probably not of bovine origin.

Factors responsible for this undue prevalence of tuberculosis among the Winnebago are the extremely bad home sanitation, ignorance of personal hygiene, harmful social customs including the use of stimulants such as peyote, and venereal infections.

The Housing Act in Holland gives financial support to public utility societies of workmen or of persons belonging to the middle classes who are desirous of building dwelling houses for their own use. The houses remain the property of the building associations. The State support consists of a loan to the amount of the total building cost at low interest and a further contribution if the cost is so high that the tenants cannot afford the consequent high rent. At the present time 60,000 dwellings are actually needed, the population of the Netherlands being about 6,800,000.

## The Physiology of Protein Metabolism

"The Physiology of Protein Metabolism," by E. P. Cathcart, M.D., is a revision of the preceding edition published in 1912 which is one of the series of monographs on biochemistry. No one who is interested in the subject and who has read the first edition can fail to appreciate the author's sincere effort in the critical collection of material and in rendering such an intricate problem exoteric.

Like the first edition, the new volume contains a full but undogmatic discussion of the various facts and theories on the physiology of protein metabolism published in current literature. The discussion in the new edition includes not only the investigations of Liebig, Voit, Pflüger Zuntz, Rubner, and their pupils, but those of the more recent workers, Lusk, Van Slyke, Folin, Osborne, Mendel, and many others.

Among the important additions to the new edition are the results of the investigations of Grafe, Underhill and Goldschmidt on the retention of ammonium nitrogen by the animal body and the experiments on the relation of the quality of proteins to protein requirements by Hopkins, Osborne and Mendel. The final chapter on the influence of carbohydrates and fats on protein metabolism is almost entirely new. Here the author summarizes the results of the investigations on the part played by carbohydrates both in vitro and in vivo and those on the influence of non-nitrogenous substances on the rate of the protein breakdown. He concludes that although there is some relation in the amounts of the various substances which can replace one another in a diet, we cannot logically refer to the replacements of the various food substances in terms of energy. The book closes with a bibliography of over eight hundred references covering a period of nearly a half century.

On the whole this is an unusually

valuable book for all those who are interested in biochemistry.

Longmans, Green & Co., 1921.

## Injuries and Diseases of the Bones and Joints

In reviewing a book, two questions should be uppermost in the mind of the reader. First, is there a definite need for such a book, and, second, how well does this particular book fill that need? It was with these two postulates in mind that the reviewer read and formulated his opinion of "Injuries and Diseases of the Bones and Joints," by Frederick H. Boetjer, M.D., and Charles A. Waters, M.D.

As to the first question, all surgeons will agree that there has been an urgent call for a book on x-ray diagnosis of the diseases and injuries of the bones and joints written in a straightforward simple manner which did not delve into ohms, watts, electrostatics, high tensions, and low tensions. There have been many books on x-ray technique and diagnosis written by roentgenologists for roentgenologists. There have also been inserted into all the latest text books on surgery chapters on x-ray diagnosis written by surgeons for surgeons. But Boetjer's and Waters' work offers the delightful combination of a book on the surgical conditions of bones and joints written for surgeons by excellent roentgenologists. Our first postulate is answered.

How well does the book fill the need? Boetjer and Waters take up their work evidently mindful of the fact that they are writing for surgeons and not x-ray technicians. They present their subject with a view of aiding in the diagnosis of plates. The text is admirably illustrated with 332 roentgenograms descriptive of the various lesions. No space is taken up with matters of technique, description of the tubes, or machines. Enumeration of some of the chapter headings will give a good idea of the structure of the book. For example, some of the chapter headings are: Normal

Bones; Fracture of Upper Extremity; Congenital Dislocations; Bone Infections; Bone Tumors. Under these headings the common conditions are first described and then the rarer conditions are taken up. A word or two of caution as to prognosis and possible errors in diagnosis are inserted.

The reviewer feels that the book fills its need so well that every surgeon who has occasion to study x-ray plates will find Boetjer's and Waters' book of great assistance.

Paul B. Hoeber, New York, 1921.

## Books Received

- DISEASES OF THE EAR, NOSE & THROAT IN CHILDHOOD.** By Douglas Guthrie, M.D. F.R.C.S., Cloth, 8vo, pp. 82, illustrated. A. & C. Black, Ltd., London, 1921.

## The Eighteenth Amendment

The problem of prohibition, its enforcement and non-enforcements affording almost as much food for thought to the pros as to the cons, is here termed a "deliberate attack not only upon our liberties but on the very foundations of our lives."

The present book by Charles Taber Stout seeks to prove the participation on the part of organized medicine in the fight for prohibition. No one for an instant could deny the active participation of great groups of men in the fight for the improvement of the social body. Nor can the desirability of this conflict be underestimated. We do not as voters and citizens know what the actual facts are and almost anything however garbled or distorted is of interest perhaps merely for its unintelligent attack.

"There is but one excuse for prohibition and that is ignorance, ignorance as to the effect on health, as a medicine. . . . With the spread of education, or rather the ability to read and write, the dissemination of false doctrines has become increasingly easy. The prohibition movement offers one of the most conspicuous examples. The health and moral plea failed."

The author turns the attack on illicit use of drugs by "organized medicine," pointing out the horrible result that "the propaganda against drugs was pushed so vigorously that it began to create a doubt in the minds of the public as to the value of drugs in the treatment of disease." Hence followed the development of drugless treatment, "physicians of health," the osteopath, the chiropractor, the dietitian, etc. The government is no longer seen as functioning for the common good but as the tool of special interests.

The way out seems to be a more thorough understanding of alcohol it-

self, its uses and abuses. Good whisky perhaps at twenty-five cents a gallon would at least give an ample supply of subjects for original research and observation. The great difficulty is that we thought we had passed this stage. When an author sagely remarks that curative medicine "stands almost exactly where it did at the beginning of the Christian era and that surgery has accomplished less than nothing," we have the feeling that he has yet a long way to go in the pursuit of knowledge. It is an uphill trudge and not always pleasant, but he who takes an infinitesimal or even negligible portion of truth well colored with preconceptions and expects to send it out as "scientific data" to convert those who honestly or dishonestly seek for more or less reasonable ways to be meeting the various problems of life may, in short, be termed wise or otherwise.

Mitchell Kennerley, New York, 1921.

## Chemical Disinfection and Sterilization

Bacteriological science has resolved itself into a struggle for existence between man and inimical microorganisms, according to the work recently brought out by Samuel Rideal and Eric K. Rideal on "Chemical Disinfection and Sterilization." The scientific principles underlying disinfection are fully set forth in this book and their application in widely diverse spheres of human life is brought out in chapters on the disinfection of air, sterilization and preservation of food, the sterilization of water, public disinfection, personal and internal disinfection, and wood preservation.

The succeeding chapters are given over to a study of the chemicals employed in disinfection, a branch of therapeutic chemistry which has not

usually been the subject of systematic treatment. The gradual immunity or acclimatization of organisms themselves to disinfectants is an important factor, as well as the proposed standardization of the growth of a particular organism for testing purposes. Such procedure, if generally adopted, would place on a comparable basis the results of different investigators.

The book closes with descriptive methods of analysis, chemical composition as well as physical condition being taken into account. To the several chapters are appended representative references which organize in a satisfactory manner the very scattered literature on the subject. A cross index adds greatly to the availability of the material.

Edwin Arnold & Co., London, 1921.

## The Treatment of Syphilis

The recent book on the treatment of syphilis by H. Sheridan Bosketel, A.M., M.D., will fill a place in the library of the busy doctor, particularly the general practitioner who is not able to visit the post-graduate schools or keep up with the technical details of advances in medical diagnosis and treatment of syphilis. As stated in the preface "It is not a volume for the skilled syphilographer—but rather is intended for the physicians who have not heretofore employed the intravenous method of injection.

The experience of the medical profession should warn general practitioners not to undertake the treatment of patients by any of the methods described without first attending a thorough course of instruction under competent specialists, and it would be unfortunate if the book stimulated the use by incompetent persons of the valuable diagnosis and treatment technic explained.

## The Health Plan for Maine—All Agencies Unite

Obligation Self-Assumed to Achieve a  
Definite Objective Within a Given Time

BY J. C. MURPHY, AUGUSTA, MAINE

THE Maine Public Health Association believes: (1) That the Health of a community is the business of the entire community and can be properly conserved only when the entire community is actively interested in solving for itself its own health problem. (2) That the solution of these problems rests basically upon the cooperation and wise supervision by the medical profession in the community and that all activities and policy in matters medical should be guided by the physicians who have as their life work the health of their people, and who have devoted years to developing in themselves a special fitness for this work. (3) That, just as the success of the physician's prescription depends upon whether or not his people obey his instructions and take his medicine, so the solving of health problems depends (a) upon the expert analysis of the situation and its needs by specially trained minds, leading to the perfection of a plan of relief and remedy—and (b) upon the organization of the people behind the plan of remedy to the point of actual cooperation and devotion to that plan. Thus has evolved the "Health Plan for Maine."

It is a plan of endeavor—a something to go by—something concrete to set before the people of the state when soliciting their cooperation and interest. A sort of synopsis of what the Maine Public Health Association

*The "Health Plan for Maine" is a concrete endeavor under expert guidance on the basis of a comprehensive study of all underlying conditions. All agencies are represented and mutual responsibility of each to the central organization is assumed. The benefits of health are claimed for the whole people. Group problems are met by group measures. The plan is unique in its comprehensiveness and in the unity of purpose which marks this community enterprise.*

hopes to accomplish within a stated period of time—so that without the necessity of any technical study of the question, any layman may grasp quickly—just what the Maine Public Health Association stands for—what is being done and what is needed in the way of health work for the state of Maine during the next three years.

The health plan for Maine is not intended as a panacea for all ills; it is not held up as an ideal nor as an all-inclusive, faultless criterion for all health endeavor everywhere. It is plainly and simply the plan of work which it was found from intensive study and conference with every important representative group in the state, was most needed at the present

time in the state of Maine and which the Maine Public Health Association can reasonably hope to accomplish within the next three years. It is a program of work which will be comprehensive of the essential needs of various localities in the state, yet thoroughly practical and flexible in its application, a program which will provide for doing first the things that are most needed—proceeding step by step in logical sequence—a program which will guard as much as possible against overlapping and duplication of effort, a program in which "cooperation" is the watchword and "Health and Happiness" the keynote.

Two years ago, the Maine Anti-Tuberculosis Association, together with several existing health agencies doing health work along specific lines, such as cancer control, eye conservation, mental hygiene, dental hygiene, social diseases, etc., and all of the volunteer health agencies were harmonized into one association so that all duplication of efforts and expenditures of time and money might be eliminated. The amalgamation was termed, the Maine Public Health Association. Headquarters were established at the capitol city, Augusta, with Dr. E. D. Merrill of Foxcroft, Me., as the President. Walter D. Thurber of Augusta is the executive secretary.

Early last summer, at the request of the Maine Public Health Association, delegates from many of the lead-

ing Maine organizations, joined with the Maine Public Health Association in formulating the health plan for Maine. These delegates served as a State Citizens Committee which was composed of officers and members of the Maine Medical Association, the Associated Industries of Maine, the Maine State Federation of Labor, the Maine State Grange, the Maine State Federation of Women's Clubs, the Maine State Chamber of Commerce, the Maine State Nurses' Association, the Maine State Department of Health, the Maine State Department of Education, editors of many Maine newspapers, bankers, ministers, lawyers and many others. At this initial conference—the Maine Public Health Association submitted a tentative plan which had been formulated after much intensive study and which had been passed upon by its Medical Advisory Committee from the Maine Medical Association. The tentative plan was submitted to each representative delegate—and copies of the same tentative plan were in turn submitted to numerous local groups represented by the State Committee. An appeal coming from a friend is much stronger than the same appeal coming from a vague commission or committee somewhere miles away from your own community. These local groups were told their community's needs must be incorporated in the plan to make it comprehensive of the entire state. They were told their State Organization was actively cooperating. They were told that no part of the Health Plan for Maine would be forced upon any community. Only the phase of the Plan which relates specifically to the needs of that community and which the community itself realized as being needed would be undertaken.

This broadcast seeking for help and guidance in the formulation of the Health Plan resulted in hundreds of letters from men and women in all walks of life, teeming with suggestions and intelligent interest and promises of personal cooperation.

Several conferences with the various groups were held during the Summer and Fall of 1921 and after a final supervision and seal of approval by the Medical Advisory Committee of the Maine Public Health Association, composed of duly appointed members of the Maine Medical Association—the Health Plan for Maine was launched in December, 1921.

The essentials of the plan are these:

(1) Every community in the state to receive the services of a public

health nurse so that mothers, particularly in the rural sections of the state, will be intelligently advised and assisted in the care of self and child both before and after birth. Each nurse will also include in her daily work, bedside nursing—in cooperation with the local physicians—proper feeding and care of the growing child, a watchful eye in her community for contagious diseases, home talks and public lectures on health matters before representative organizations in her community.

(2) Every school child in the state enrolled as a Modern Health Cru-

All the leading Maine organizations united in the summer of 1921, forming the Maine Public Health Association, with headquarters at Augusta, Me., and with Dr. E. D. Merrill, of Foxcroft, Me., as president.

sader. Thirty-two thousand are now enrolled; ninety thousand are yet to be enrolled. This means teaching health habits by means of the child's love of pageantry and ceremony. Continued active cooperation between the Maine Public Health Association and the State Department of Education will make this possible.

(3) Development of industrial medical and nursing supervision in larger industries in cooperation with the Associated Industries of Maine.

(4) Continuation of postgraduate clinics for Maine physicians in cooperation with Maine Medical Association. Every physician in the state will thus have the privilege of listening to the newest and best achievements in medicine, methods of diagnosis, etc. Leading specialists from all parts of the country are brought to these clinics for lectures and demonstrations to our local physicians.

(5) Educational campaign by

which it is hoped to accomplish health talks in every local, social, fraternal, labor, commercial, and civic organization in the state, by means of moving pictures, stereopticon slides, lectures, exhibits, distribution of literature, public speakers etc. In developing this phase of The Plan active cooperation will maintain between the Maine Public Health Association and the State Department of Health, the Maine State Grange, the Maine State Federation of Labor, the Maine Department of the American Legion, the State Department of Education, the Maine State Federation of Women's Clubs, and other organizations.
